
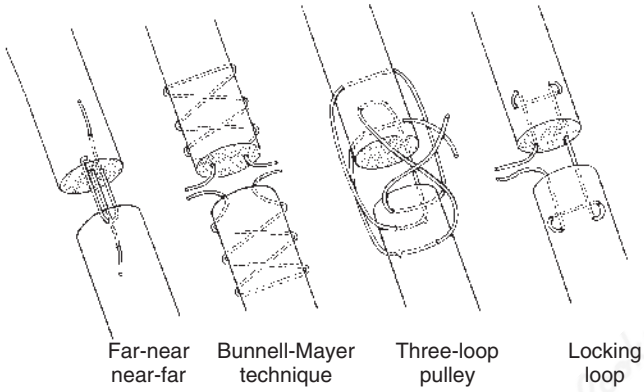

FIG. 35.4 Suture patterns used to appose tendon ends.

under investigation as an aid in the healing of muscle and tendon in dogs (see Chapter 31).

Physical Rehabilitation

After immobilization for muscle or tendon lacerations, physical rehabilitation is vital to reverse the effects of immobilization on the other joints (see Chapter 11). The animal should be gradually returned to normal activity; premature weight bearing will result in failure of the tendon to heal.

PROGNOSIS

Return to normal function is expected if postoperative recommendations are followed. Failure is generally associated with allowing the animal to exercise before the tendon has completely healed.

MANAGEMENT OF SPECIFIC MUSCLE AND TENDON CONDITIONS

ACHILLES TENDON RUPTURE

DEFINITIONS

Rupture of the muscle-tendon unit is a complete or partial loss of integrity of the muscle-tendon unit caused by extreme overstretching. Muscle ruptures are caused by powerful contraction during forced hyperextension of the muscle-tendon unit.

GENERAL CONSIDERATIONS AND CLINICALLY RELEVANT PATHOPHYSIOLOGY

Achilles tendon ruptures are seen most often in sporting and performance athlete breeds; however, any breed may be affected. The injury may be a partial or complete rupture of the Achilles tendon. Injury of the Achilles mechanism may arise from an acute traumatic episode or from chronic progressive stretching of the tendon. The former often occur secondary to a fall, or a penetrating wound or laceration secondary to automobile trauma, bite wounds, or from contact with a sharp object, such as the edge of a ski. Conversely, chronic injuries are often secondary to overuse that causes chronic stretching and deterioration of the tendon. Chronic injuries more commonly occur in sporting breeds (e.g., field trial dogs and bird hunting dogs) and are often bilateral. Bilateral chronic degeneration of the common calcanean tendons is relatively common in Doberman pinschers, although the cause is unknown.

DIAGNOSIS

Clinical Presentation

Signalment

Any age, breed, or sex of dog or cat may be affected. Athletic dogs are most commonly affected.

As noted previously, Doberman pinschers may have idiopathic bilateral common calcanean tendon degeneration.

History

Affected animals usually exhibit weight-bearing lameness after strenuous activity.

Physical Examination Findings

Tarsal hyperflexion is often noted in animals with Achilles tendon rupture (Fig. 35.5A–B and Video 35.1). The animal is unable to bear weight if the injury occurs secondary to acute trauma, and flaccidity of the Achilles tendon is noted on passive dorsal flexion of the tarsus when the stifle is extended (Video 35.2). If the injury occurs secondary to chronic stretching of the Achilles tendon, the patient will be weight bearing but will walk plantigrade because of hyperflexion of the tarsus. Patients with chronic Achilles tendon injury show varying degrees of tarsal hyperflexion depending on the length of time the injury has been present. If the entire tendon complex is involved, the tarsus and the digits hyperflex; if the tendon of the superficial flexor muscle is not involved, the tarsus will hyperflex and the digits will flex (see Fig. 35.5B). Postural changes associated with palpable swelling of the Achilles tendon confirm the diagnosis. Occasionally, the injury occurs at the myotendinous juncture. Postural changes and careful palpation of the muscle-tendon unit confirm the diagnosis. Doberman pinschers have tarsal hyperextension and swelling of the common calcanean tendon.

FIG. 35.5 (A) Tarsal hyperflexion (plantigrade stance) due to Achilles tendon rupture. (B) Tarsal hyperflexion with digital flexion due to Achilles tendon rupture with intact superficial digital flexor.

Diagnostic Imaging

Ultrasonography can help determine the location of tendon fiber disruption and may differentiate between partial and complete tears. Ultrasound may also be useful in evaluating healing after surgery. Standard craniocaudal and medial-to-lateral radiographs are indicated to determine whether bone avulsion is present or not.

Laboratory Findings

Consistent laboratory abnormalities are not found.

DIFFERENTIAL DIAGNOSIS

Sciatic nerve injury, tarsal collapse secondary to immune-mediated arthropathy, endocrinopathy, and congenital tarsal hyperflexion must be differentiated from Achilles tendon rupture. Gentle palpation of the muscle-tendon unit reveals loss of continuity and/or an area of swelling with tendon rupture, whereas patients with congenital tarsal hyperflexion lack these findings. When nerve injury is present, neurologic examination will show sciatic reflexes to be absent or decreased.

MEDICAL MANAGEMENT

Surgical repair of completely ruptured tendons is indicated; medical management is not. External coaptation may be tried with partial rupture, but results are usually unsatisfactory. Doberman pinschers with common calcanean tendon degeneration should be treated conservatively with exercise moderation and bandaging or orthotics as necessary to protect the tarsus. Splints are rarely beneficial. Physical rehabilitation may accelerate tendon healing (see Chapter 11).

SURGICAL TREATMENT

Surgical repair involves primary anastomosis of the tendon (tenorrhaphy) or reinsertion of the tendon on the calcaneus. Augmentation of a primary repair using a variety of materials (such as semitendinosus muscle and composite suture) has been described.[1]

Preoperative Management

Activity should be limited until definitive treatment is begun. Open wounds (e.g., laceration of the Achilles tendon) should be cleaned and covered with a sterile dressing.

Anesthesia

Anesthetic management of animals with orthopedic disease is discussed on p. 976.

Surgical Anatomy

The Achilles tendon unit is composed of tendons arising from the gastrocnemius and superficial digital flexor muscles along with a common tendon from the semitendinosus muscle, the gracilis muscle, and the biceps femoris muscle. The common tendon of the gastrocnemius muscle is the major component of the Achilles tendon with acute injury. One can identify each component of the acutely injured Achilles complex and can suture each individually. However, with chronic injury, the tendon ends retract, leaving a void to be filled with fibrous tissue. Identification of each component is not possible. The complex (fibrous scar and Achilles tendon) is treated as a single structure.

Positioning

Position the patient in sternal or lateral recumbency. The limb may be extended beyond the end of the table for sterile preparation and surgery. For Achilles tendon injury, clip and prepare the limb for surgery from proximal to the stifle joint to the phalanges distally.

SURGICAL TECHNIQUE

Achilles Tendon Rupture

Make an incision over the site of injury on the caudolateral surface of the limb. If the injury is acute, identify the three tendons composing the Achilles complex, and suture each tendon separately with an interrupted far-near, near-far pattern (see Fig. 35.4) using nonabsorbable, small-diameter (3-0 to 4-0, depending on the size of the animal) monofilament suture. If the injury is chronic and identification of individual tendon units is not possible; continue surgical dissection to expose the circumference of the thickened fibrous band. Then sequentially remove sections of scar tissue from the center of the mass. Remove enough tissue so that tension is present in the Achilles complex when the stifle joint is in a normal standing position and the tarsus is slightly extended. Be careful to avoid removing too much of the proliferative fibrous tissue. If excess fibrous tissue is excised, apposition of the cut ends will be difficult. *Suture the cut ends with a three-loop pulley pattern (see Fig. 35.4).*

Achilles Tendon Avulsion

Achilles tendon avulsion from the calcaneus is treated by suturing the tendon as described earlier and securing it to the calcaneus by passing the suture through holes drilled through the proximal calcaneus.

Whether the injury is acute or chronic and involves rupture or avulsion of the tendon, support of the tendon anastomosis is critical for a favorable outcome. Support is provided by immobilization of the tarsal joint in slight extension. *Place a raised, threaded transfixation pin through the free end of the calcaneus into the distal tibia. Cut through the pin shaft to leave the pin just below the skin surface. Provide additional support with a fiberglass cast. Alternatively, immobilize the hock in slight extension with external fixators by placing transfixation pins through the distal tibial diaphysis and the calcaneus, connecting them with bilateral external fixator bars.*

FiberLoop Repair

Achilles tendon avulsions or low lacerations may be treated by anastomosis of the distal tendon to the calcaneus with a fiberwire loop pattern to a calcaneal bone tunnel and surgical button. *Make an incision over the site of injury on the caudal surface of the limb. Identify the tendons composing the Achilles complex. Pass a stay suture through the distal aspect of the Achilles tendon. Using a FiberLoop (Arthrex), perform 4 or 5 nonlocking loops (baseball stitch or SpeedWhip [Arthrex]) on the distal aspect of the Achilles tendon. (Fig. 35.-6A) Drill a distal to proximal bone tunnel through the caudal-proximal aspect of the calcaneus. Pass the FiberLoop needle from proximal to distal through the hole and secure the Fiberwire on the distal aspect by suturing over a surgical button (Fig. 35.6B–C). Have the hock joint in full extension when tying the suture over the button. If the injury was a distal laceration, suture the proximal and distal aspects of the Achilles tendon with nonabsorbable suture in an interrupted pattern. Close the surgical wound routinely and place the limb in a bivalved cast with the hock joint in extension. Maintain the cast for 4 weeks then decrease*

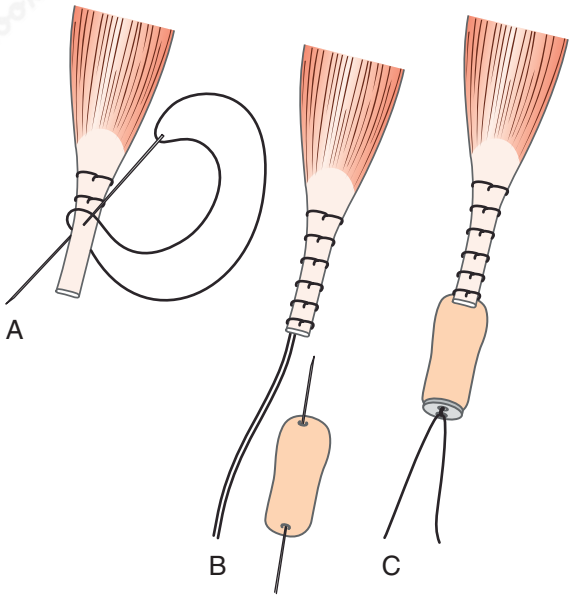

FIG. 35.6 Loop suture technique for repair of Achilles tendon trauma. (A) Secure the loop to the distal aspect of the tendon using the locking loop pattern. (B) Pass the straight needle through a hole in the proximal aspect of the calcaneus. (C) Secure the loop suture on the distal aspect of the calcaneus with a stainless-steel button.

FIG. 35.7 Protective orthotics, initially to limit tarsal flexion and gradually, to allow adjustment to increase range of motion.

to a half cast/splint for 2 weeks. Finally, place the limb in a soft padded bandage for two more weeks. PRP may be injected at the time of surgery to potentially accentuate healing (see Chapter 31). The use of a SpeedWhip technique has been compared to a three-loop pulley for repair of an Achilles tendon rupture in a canine cadaver model.[1] In this study, the three-loop pulley technique provided greater resistance to 3-mm gap formation and greater load to failure. These results are in contradiction to previous studies that showed superior biomechanical properties of SpeedWhip fixation in comparison to alternative fixation methods.

SUTURE MATERIALS AND SPECIAL INSTRUMENTS

Nonabsorbable suture material is recommended for tendon repair. Swaged-on needles are helpful in limiting tissue trauma during suturing. Self-retaining retractors are useful for holding surrounding tissue away from the working area. A power drill is useful if a bone screw or transfixation pins are to be inserted. The FiberLoop technique requires a swaged-on loop suture or suture passer.

POSTOPERATIVE CARE

The cast and transfixation pin, or external fixators are placed for 3 to 6 weeks, after which both may be removed. The limb should then be supported in a padded bandage to prevent full dorsal flexion of the tarsus. If an external fixator was used, it may be dynamized by the use of hinges or resistance bands. Hinges placed at the center of rotation of the joint can be adjusted to increase the range of motion and subsequently the tendon load. Elastic bands placed between the pins above and below the joint to replace the sidebars allow partial loading of the tendon. Alternatively, protective orthotics can be applied to initially limit tarsal extension for 2 to 3 weeks and then gradually to allow adjustment of increased range of motion over 2 to 10 weeks (Fig. 35.7). Activity should be limited to leash walking for 10 weeks. The use of PRP is under investigation as an aid in the healing of muscle and tendon in dogs (see Chapter 31).

Physical Rehabilitation

After immobilization for muscle or tendon rupture, physical rehabilitation is vital to reverse the effects of immobilization on the joints (see Chapter 11). The animal should be gradually returned to normal activity; premature weight bearing will result in failure of the tendon to heal.

PROGNOSIS

The prognosis for return to strenuous athletic activity is good to excellent. Doberman pinschers with degeneration of the common calcanean tendon often regain some degree of tendon function spontaneously over time. The tendons often remain swollen, but the degree of hock flexion and disability typically improves over several months of conservative therapy.

SUPRASPINATUS TENDINOPATHY

DEFINITION

Supraspinatus tendinopathy refers to mineralized or nonmineralized disease of the insertional tendon of the supraspinatus complex. Mineralization is the accumulation of calcified material within the insertional tendon of the supraspinatus. **Biceps tendon disease** (tendinopathy, tendinitis) is a general term that incorporates various types of injury, including tearing of the tendon and inflammation of the tendon and surrounding synovial sheath.

GENERAL CONSIDERATIONS AND CLINICALLY RELEVANT PATHOPHYSIOLOGY

The cause of mineralization of the supraspinatus tendon is unknown, but it may be associated with aging, overuse, trauma, or hypoxia secondary to hypovascularity of the supraspinatus tendon. Histopathology demonstrates myxomatous degeneration and chondroid metaplasia, which are characteristics of tendon degeneration. Mineralization may also be associated with tearing of tendon fibers. Severe disease may be associated with a mass of mineral and fibrous tissue compressing or deviating the biceps tendon in the bicipital groove. Disease of the biceps and the supraspinatus may occur together, and thickening of the supraspinatus may displace the biceps tendon, resulting in inflammation and pain.[2] In the most severe cases, other diseases of the shoulder (e.g., instability, osteoarthritis) may also be identified; thus shoulder arthroscopy should be performed in dogs with suspected supraspinatus tendinopathy. Radiographic mineralization is a common incidental finding and is not associated with clinical lameness; therefore accurate determination of the cause of the lameness is critical.

DIAGNOSIS

Clinical Presentation

Signalment

Athletic large breed dogs are affected most commonly.

History

Lameness may be mild or severe depending on the severity of the lesion. Most animals have a chronic history of lameness.

Physical Examination Findings

Palpation on the medial aspect of the greater tubercle may cause pain. This response may be magnified by shoulder flexion.

Diagnostic Imaging

Ultrasonography helps evaluate stabilizers of the scapulohumeral joint (i.e., biceps and supraspinatus tendons). In cases of injury to the supraspinatus tendon, ultrasound helps determine the degree of tendon fiber disruption. Mineralization of the tendon appears as hyperechoic foci, which cause distal acoustic shadowing. The most common ultrasound finding in dogs with supraspinatus tendinopathy is enlargement of the tendon of insertion. With radiography, mineralization within the supraspinatus tendon may be seen adjacent to the greater tubercle using a skyline view (Fig. 35.8). Osteophytosis of the intertubercular groove may be apparent and may be due to irritation of the biceps tendon and tendon sheath caused by the enlarged supraspinatus tendon, leading to secondary arthritis. MRI demonstrates enlargement and increased signal in the area of insertion of the supraspinatus tendon.[2]

Laboratory Findings

Consistent laboratory abnormalities are not found.

DIFFERENTIAL DIAGNOSIS

Mineralization of the supraspinatus tendon must be differentiated from other shoulder diseases, including biceps tendinopathies. Differential diagnoses include biceps tenosynovitis, osteochondritis dissecans, shoulder instability, and shoulder osteoarthritis.

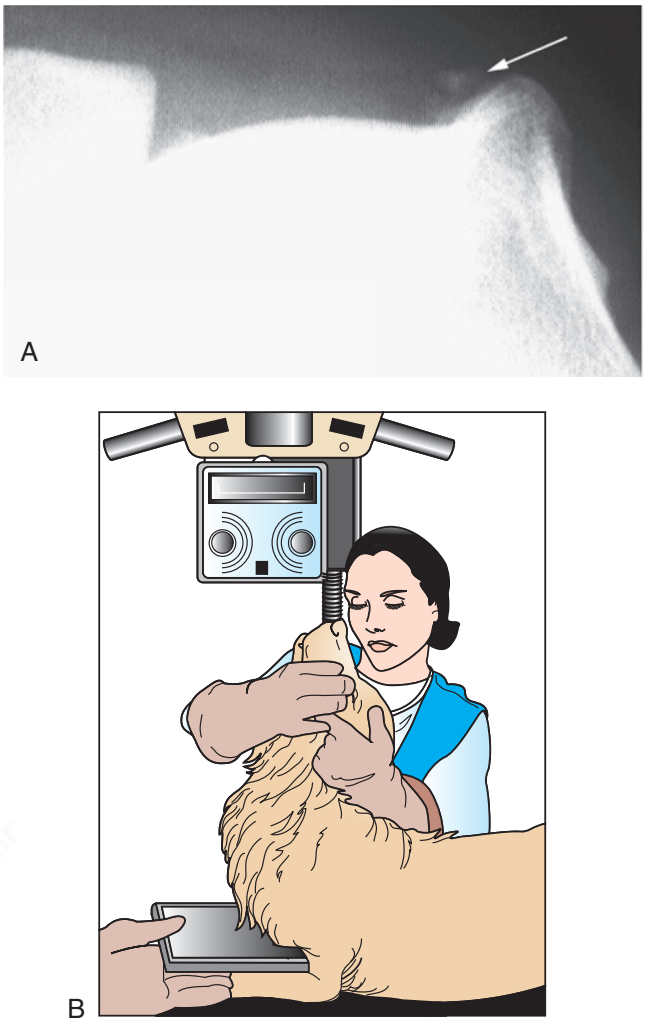

FIG. 35.8 (A) Mineralization of the supraspinatus tendon *(arrow)*. (B) Radiographic positioning is attained with the patient in sternal recumbency and the head extended out of the beam. The cassette is placed above the antebrachium with the humerus nearly vertical. The radiographic beam courses down the bicipital groove.

MEDICAL MANAGEMENT

Medical management of supraspinatus mineralization is often attempted first. Glucocorticoid injections combined with rest are often attempted and may provide temporary relief. Injection of glucocorticoids into the tendon may cause tendon degeneration; therefore multiple injections are not recommended. The use of PRP in the treatment of supraspinatus tendinopathy is currently being investigated (see Chapter 31).

Physical Rehabilitation

Physical rehabilitation for mineralization includes cryotherapy and passive range of motion. Therapeutic ultrasound may aid in eliminating mineral deposits in the muscle (see Chapter 11).

SURGICAL TREATMENT

Surgery is recommended for confirmed mineralization of the supraspinatus tendon that is unresponsive to medical management. Complete evaluation of the shoulder joint is needed to rule out other associated diseases. Arthroscopy of the shoulder joint is the most efficient means of thoroughly evaluating the joint including the biceps tendon. Surgical treatment involves removal of the mineral from the tendon of insertion of the supraspinatus, resection of diseased tendon, and multiple longitudinal tenotomy. Longitudinal tenotomy may decrease intratendinous pressure, increase vascularization of the critical zone, and induce healing, thus improving or reversing degeneration.

Preoperative Management

Activity should be limited until definitive treatment is initiated.

Anesthesia

Anesthetic management of animals with orthopedic disease is discussed on p. 976.

Surgical Anatomy

The supraspinatus tendon has a broad insertion on the medial and lateral aspects of the greater tubercle. The medial portions are adjacent to the biceps tendon.

Positioning

Position the patient in lateral recumbency. A hanging-leg preparation facilitates manipulation of the limb during surgery. Clip and prepare the limb for surgery from the dorsal midline to the mid-antebrachium.

SURGICAL TECHNIQUE

Perform shoulder arthroscopy to evaluate the remainder of the joint. Perform a craniomedial approach to the shoulder joint and biceps tendon (see Fig. 34.23). Identify and remove the mineralized area or diseased area within the insertional tendon of the supraspinatus. To perform a longitudinal tenotomy, make multiple full-thickness longitudinal incisions in the tendon of insertion with a surgical blade. Close the surgical site routinely.

SURGICAL MATERIALS AND SPECIAL INSTRUMENTS

Gelpi retractors are useful for maintaining exposure to the craniomedial portion of the shoulder joint.

POSTOPERATIVE CARE

Activity should be limited to leash walking for 8 to 10 weeks.

Physical Rehabilitation

Physical rehabilitation can be started immediately after surgery and should include cryotherapy for the first 72 hours, followed by passive flexion and extension of the limb and heat therapy (see Chapter 11). Specific controlled exercises should be used to regain maximum function.

PROGNOSIS

The prognosis for return to normal function is fair to good, depending on the presence of other shoulder diseases.

INFRASPINATUS FIBROTIC CONTRACTURE

DEFINITIONS

Muscle contracture or **fibrosis** may occur when normal muscle-tendon unit architecture is replaced with fibrous tissue, resulting in functional shortening of the muscle or tendon. This shortening may cause abnormal motion in adjacent joints.

GENERAL CONSIDERATIONS AND CLINICALLY RELEVANT PATHOPHYSIOLOGY

Infraspinatus muscle contracture occurs most often in hunting dogs after irreversible muscle fiber injury. The cause is unknown but appears to be a primary muscle disorder rather than a neurologic or immune-mediated disorder. Histologic findings (e.g., degeneration, atrophy, fibroplasia) within damaged areas of the muscle are compatible with severe strain. Disease progression is associated with breakdown of muscle fibers and replacement by fibrous tissue that causes muscle contracture and external rotation and abduction of the limb.

DIAGNOSIS

Clinical Presentation

Signalment

Contracture of the infraspinatus muscle usually occurs in young, adult, sporting breeds.

History

Acute lameness after strenuous activity in the 3 weeks before evaluation for infraspinatus muscle contracture is typical.

Physical Examination Findings

Animals with infraspinatus muscle contracture initially have weight-bearing unilateral forelimb lameness (Video 35.3).[3] Soft tissue swelling around the shoulder joint may be noted. Lameness usually resolves and is absent for 3 to 4 weeks, but then mild lameness and a gait abnormality develop. The characteristic gait abnormality occurs secondary to progressive fibrosis and contracture of the infraspinatus muscle. As the muscle shortens from contracture, external rotation of the shoulder causes elbow abduction and outward rotation of the paw (Fig. 35.9).

Diagnostic Imaging

Ultrasonography helps evaluate stabilizers of the scapulohumeral joint. The normal infraspinatus tendon should show a typical arrangement of parallel, echogenic striae against a hypoechoic background on ultrasound. Acute injury may demonstrate fiber pattern disruption with edema and hemorrhage. Chronic muscle contracture varies in appearance depending on the severity and the stage of the disease. Fibrosis of the muscle is visible as increased echogenicity of the tendon. MRI of infraspinatus contracture demonstrates heterogeneous signal intensity within the muscle and at the musculotendinous junction, with minimal extension into the tendon.[3]

DIFFERENTIAL DIAGNOSIS

Diagnosis of infraspinatus muscle contracture is usually possible from historical and physical examination findings. In the acute phase of injury, inflammation of the infraspinatus tendon must

FIG. 35.9 Dog with infraspinatus muscle contracture. Note external rotation of the shoulder and internal displacement of the elbow.

be differentiated from other causes of forelimb lameness, particularly those of the shoulder region.

MEDICAL MANAGEMENT

Physical rehabilitation may help prevent contracture if the condition is diagnosed and treated early; however, presentation to a veterinarian at this stage is uncommon, and surgical therapy at the contracted stage is highly successful. Thus surgical treatment is most commonly performed in affected dogs.

Physical Rehabilitation

Physical rehabilitation entails ultrasound therapy combined with stretching and passive range of motion (see Chapter 11).

SURGICAL TREATMENT

Surgical treatment is directed at releasing the fibrotic myotendinous infraspinatus muscle as it crosses the shoulder joint. Surgical treatment (fascial decompression) at the reported early stage (compartment syndrome) has been described in one dog.

Preoperative Management

These animals are otherwise generally healthy, and minimal preoperative care is necessary.

Anesthesia

See p. 976 for anesthetic management of animals with orthopedic disease.

Surgical Anatomy

The infraspinatus muscle-tendon unit is a cuff muscle of the shoulder joint (see Fig. 34.19). The muscle lies next to the scapula, just caudal to the spine. The tendon crosses the joint craniolaterally to insert just distal to the greater tubercle of the proximal humerus. At surgery, the tendon appears thickened and, because of fibrous tissue invasion, has an off-white color rather than the white, glistening appearance typical of normal tendons. The muscle is atrophied and appears pale relative to normal, healthy muscle.

Positioning

Clip the shoulder from the dorsal midline to the elbow, and position the patient in lateral recumbency.

SURGICAL TECHNIQUE

Perform a craniolateral approach to the shoulder joint. Isolate the circumference of the infraspinatus muscle with sharp dissection (see Fig. 34.19). Transect the fibrotic muscle and any fibrous bands restricting movement of the joint. Once the fibrous contracture is incised, the limb will assume a normal position, and a normal range of motion of the shoulder will be possible.

SUTURE MATERIALS AND SPECIAL INSTRUMENTS

Self-retaining retractors and a periosteal elevator assist tissue retraction and reflection.

POSTOPERATIVE CARE

Special postoperative care is not required after surgery for infraspinatus muscle contracture. These animals usually begin to use the limb within a few days after surgery. The dog should be allowed to fully bear weight as soon as possible. Physical rehabilitation is important to help the animal regain full usage of the limb (see Chapter 11).

PROGNOSIS

The prognosis for infraspinatus muscle contracture is excellent, and return to preinjury function is expected after surgery.

QUADRICEPS CONTRACTURE

DEFINITIONS

Muscle contracture or **fibrosis** *(quadriceps tie-down, fracture disease of the rear limb)* may occur when normal muscle-tendon unit architecture is replaced with fibrous tissue, resulting in functional shortening of the muscle or tendon. This shortening may cause abnormal motion in adjacent joints. **Myopathy** is another term used to describe muscle disease.

GENERAL CONSIDERATIONS AND CLINICALLY RELEVANT PATHOPHYSIOLOGY

Quadriceps muscle contracture usually occurs after distal femoral fracture in young dogs; however, congenital contracture of the quadriceps muscle has been reported. Inadequate fracture stabilization, excessive tissue trauma during surgery, or prolonged limb immobilization with the stifle in extension may singly or in combination contribute to quadriceps contracture. It is often associated with Salter-Harris type I or II fracture in puppies (see p. 984). Quadriceps contracture may occur after splinting in extension for as little as 5 to 7 days. The disease is likely a result of the combination of muscle trauma, rapid bone callus formation, and limb immobilization. Joint stiffness develops because of

fibrous adhesions between the quadriceps and the fracture callus. With time, adhesions form between the joint capsule and the distal femur, limiting limb use and causing the quadriceps muscle to atrophy. In later stages, the disease also causes bone atrophy, atrophy of cartilage in the stifle, intraarticular fibrosis, and eventual ankylosis of the stifle joint. The cause of congenital quadriceps contracture and the reason why contracture occurs most commonly in young dogs are unknown.

DIAGNOSIS

Clinical Presentation

Signalment

Any age, breed, or sex of dog may develop quadriceps muscle contracture; however, it most commonly occurs in immature patients after distal femoral fracture when inappropriate repair has been done and/or postoperative physical rehabilitation has been inadequate.

History

Animals with quadriceps muscle contracture are usually evaluated for lameness 3 to 5 weeks after sustaining femoral trauma. Frequently, internal reduction and stabilization of a distal femoral fracture or application of an external splint (such as a Thomas splint) for stabilization of a femoral fracture has been performed.

Physical Examination Findings

The stifle joint of animals with quadriceps muscle contracture has a limited range of motion (Fig. 35.10 and Video 35.4). Initially the joint can be fully extended, but it can be flexed only 20 to 30 degrees. Gradually the amount of flexion decreases to less than 10 degrees. Contracture may be such that the stifle joint appears hyperextended. Cranial thigh muscles are generally atrophied and palpated as a thickened cord.

Diagnostic Imaging

Radiography shows evidence of a healing distal femoral fracture. Ultrasound of the normal quadriceps muscle should show a typical echogenic, fibrillar arrangement. Changes in this arrangement vary depending on the type, severity, and stage of trauma.

FIG. 35.10 Dog with quadriceps muscle contracture. Note hyperextension of the femur.

Laboratory Findings

Consistent laboratory abnormalities are not present.

DIFFERENTIAL DIAGNOSIS

The diagnosis of quadriceps contracture can usually be made from historical and physical examination findings.

MEDICAL MANAGEMENT

Prevention of quadriceps contracture should begin within 24 hours of surgery for distal femoral fracture in puppies (see Chapter 11). Therapy should include passive range of motion several times a day, cryotherapy, and massage for edema reduction. Tissue mobilization techniques help prevent fibrosis. Exercises to encourage weight bearing should begin approximately 3 days postoperatively and may include slow leash walking, treadmill walking, and aquatic therapy (see Table 32.7).

Physical Rehabilitation

Physical rehabilitation alone is rarely successful in the management of quadriceps contracture. Forced flexion of the stifle often results in additional fractures to the femur or tibia (see Table 32.9).

SURGICAL TREATMENT

Treatment of quadriceps contracture is aimed at restoring limb function. Release of fibrous thickening and adhesions between joint capsule and femur and between quadriceps muscle and femur is necessary. If a functional range of motion is not achieved after adhesion release, lengthening of the quadriceps muscle-tendon unit is required. Lengthening may be accomplished by a Z-plasty or by release of the origin of each muscle. Recurrence of contracture with resultant loss of stifle joint motion occurs if preventive rehabilitation measures are not taken after surgery. An effective method of maintaining a functional range of stifle motion is to apply a transarticular fixator postoperatively to maintain passive flexion of the stifle joint, while allowing active or passive extension.[4] Alternatively, if sufficient flexion is obtained at surgery, a 90/90 bandage can be used.

Preoperative Management

These animals are otherwise generally healthy, and minimal preoperative care is necessary.

Anesthesia

See p. 976 for anesthetic management of animals with orthopedic disease.

Surgical Anatomy

The quadriceps muscle-tendon unit is composed of the vastus medialis, vastus intermedius, rectus femoris, and vastus lateralis muscles. These muscles all atrophy in patients with quadriceps muscle contracture. Proximally, the rectus femoris muscle palpates as a thickened cord. At surgery, all four muscles of the quadriceps appear small and pale in color. In patients with distal femoral fractures, the atrophied muscles lie superficial to, and are intertwined with, proliferative fibrous tissue. Normal range of motion in the stifle joint is from 180 degrees (full extension) to 30 degrees (full flexion).

Positioning

Clip the limb from the dorsal midline to the tarsus, and position the patient in lateral recumbency. A hanging-leg preparation facilitates manipulation of the limb during surgery.

SURGICAL TECHNIQUE

Expose the stifle joint and the distal femur through a liberal craniolateral incision (see Fig. 34.113). Elevate and release adhesions between the quadriceps muscle group and the femur with sharp dissection. Release adhesions between the fibrous joint capsule and the femoral condyles. Luxate the patella medially, and flex the joint to its full extent. If a functional range of motion (greater than 40 degrees) is not achieved after the adhesions are released, perform a quadriceps muscle-tendon unit lengthening procedure.

Z-Plasty

Make a longitudinal incision through the center of the muscle-tendon unit beginning 8 to 10 cm proximal to the patella. Extend the incision distally to a point 3 cm proximal to the patella. At the proximal extent of the longitudinal incision, make a transverse incision laterally through the muscle and fibrous tissue. At the distal extent of the longitudinal incision, make a transverse incision medially through the muscle and fibrous tissue. Flex the stifle, and allow the cut edges of the longitudinal incision to slide on each other. When a functional range of flexion is achieved, place interrupted sutures across the longitudinal incision to maintain the desired length of the quadriceps muscle-tendon unit.

Muscle Release

Extend the lateral incision to expose the proximal femur. At the level of the third trochanter, elevate the quadriceps from the medial, lateral, and caudal surfaces of the femur. Incise through the origins of each muscle group to release the quadriceps, and allow distal sliding of the muscle group. Release the vastus intermedius near its point of origin on the ilium. Close the surgical wound using standard methods.

Transarticular Fixator

Insert a half-pin just below the third trochanter of the femur using an end-threaded transfixation pin, and insert a full pin through the tibia 4 cm above the tarsus, using a centrally threaded transfixation pin. Maximally flex the stifle joint, and maintain this position with a heavy rubber band connecting the proximal and distal transfixation pins. Fashion a bandage around the paw, and connect it to the distal transfixation pin to maintain a functional angle of the tarsus.

SUTURE MATERIALS AND SPECIAL INSTRUMENTS

Self-retaining retractors and a periosteal elevator assist tissue retraction and reflection. Instruments for placement of pins are necessary if a transarticular fixator is placed postoperatively.

POSTOPERATIVE CARE AND ASSESSMENT

After application of a transarticular fixator for quadriceps muscle contracture, pin-to-skin interfaces must be cleaned daily (see p. 1002). Passive flexion and extension of the stifle joint and tarsus should begin as soon as the patient allows limb manipulation (see Table 32.7). Joint movement should be repeated 20 to 30 times and at least three times daily; increased frequency of manipulation improves rehabilitation. The external fixator should be maintained for 3 to 5 weeks. Physical rehabilitation should be continued for an additional 5 weeks after it is removed. If a 90/90 flexion bandage is applied, it should be maintained for 3 weeks. After bandage removal, passive flexion and extension of the joint should be performed as described previously.

PROGNOSIS

The prognosis after surgery for quadriceps muscle contracture is guarded and depends on the degree of degenerative joint changes present and on whether a functional range of motion is obtained at surgery.[4] The prognosis is fair for functional limb use, but contracture may recur following surgery. A normal range of motion is seldom achieved, and most animals are able to flex the stifle only 45 to 90 degrees.

GRACILIS AND SEMITENDINOSUS FIBROTIC MYOPATHY

DEFINITIONS

Muscle contracture or **fibrosis** may occur when normal muscle-tendon unit architecture is replaced with fibrous tissue, resulting in functional shortening of the muscle or tendon. This shortening may cause abnormal motion in adjacent joints. Synonyms include *hamstring contracture, gracilis* or *semitendinosus contracture,* and *gracilis* or *semitendinosus myopathy*. **Myopathy** is a general term used to describe disease of the musculature.

GENERAL CONSIDERATIONS AND CLINICALLY RELEVANT PATHOPHYSIOLOGY

Gracilis or semitendinosus fibrotic myopathy occurs most often in German shepherd dogs or Belgian shepherds. Fibrotic myopathy of the iliopsoas and the sartorius muscles has also been reported.[5,6] The cause of fibrotic myopathy is unknown but is hypothesized to be trauma, immune-mediated disease, or neuropathy. The musculotendinous junction is consistently thickened and fibrotic. A fibrous band is associated with the caudolateral border of the gracilis muscle. The muscle fibers are replaced with dense fibrous connective tissue, causing a nonpainful lameness. Approximately 50% of dogs have bilateral limb involvement.

DIAGNOSIS

Clinical Presentation

Signalment

Gracilis or semitendinosus myopathy occurs in young adult, male German shepherds and in Belgian shepherds. Traumatic gracilis muscle injuries occur in greyhounds.

History

Usually a history of insidious onset of rear limb lameness is characterized by an altered gait associated with gracilis or semitendinosus myopathy.

Physical Examination Findings

Dogs with gracilis or semitendinosus myopathy have a shortened stride, rapid elastic medial rotation of the paw, external rotation

FIG. 35.11 Circumduction gait due to gracilis or semitendinosus fibrotic myopathy.

of the hock, and internal rotation of the stifle during the mid- to late-swing phase of the stride ("circumduction gait") (Fig. 35.11 and Video 35.5). The lameness is more pronounced at a trot. Affected muscles are palpable as a distinct taut band differentiated by the location of origin. Some dogs are in pain on muscle palpation. Most dogs exhibit a nonpainful lameness. Abduction of the hip and extension of the stifle and hock may be limited.

Diagnostic Imaging

Radiography is not usually helpful in these cases. Ultrasound examination is typically used to determine the extent and severity of the abnormality.

Laboratory Findings

Consistent laboratory abnormalities are not present.

DIFFERENTIAL DIAGNOSIS

The diagnosis of gracilis or semitendinosus myopathy can usually be made from historical and physical examination findings. Sartorius muscle contracture is less common but must be differentiated from them. Differentials include hip dysplasia, cranial cruciate ligament injury, and neurologic disease.

MEDICAL MANAGEMENT

If muscle trauma is identified early (especially in greyhounds), intermittent rest and ice (15 minutes on, 15 minutes off) may minimize permanent muscle damage. Following acute injury, strengthening and range-of-motion exercises should be performed while additional muscle trauma is minimized.

Physical Rehabilitation

Physical rehabilitation alone is rarely successful in the management of chronic contracture of the hamstring or gracilis muscles; it should be combined with surgery.

SURGICAL TREATMENT

Gait abnormalities observed with gracilis or semitendinosus myopathy can be reversed temporarily by resecting the affected muscles; however, the fibrotic band and subsequent lameness usually recur in 2 to 4 months. When surgery is attempted, it must be combined with aggressive, long-term rehabilitation, particularly during the period of fibrous tissue maturation (approximately 3–6 weeks postoperatively).

Preoperative Management

These animals are otherwise generally healthy, and minimal preoperative care is necessary.

Anesthesia

See p. 976 for anesthetic management of animals with orthopedic disease.

Surgical Anatomy

The gracilis muscle originates on the pubic symphysis and inserts along the medial tibial crest, but continues as crural fascia, finally joining with the semitendinosus to contribute to common calcaneal or Achilles tendons, essentially crossing the hip and stifle joints and inserting on the calcaneus. The semitendinosus muscle originates on the tuber ischium and follows a similar course, inserting on the medial portion of the tibia, continuing as crural fascia, and inserting on the tuber calcis. Fibrotic muscle can be palpated before surgery. Affected muscle may be fibrotic throughout its length; more commonly, the distal myotendinous junction of the gracilis muscle is thickened and fibrotic. A thick fibrous band associated with the proximal caudal border of the gracilis may be observed.

Positioning

Clip the rear limb from midline to tarsus, and position the animal in dorsal recumbency. Use a hanging-limb technique to facilitate limb manipulation.

SURGICAL TECHNIQUE

Incise the skin directly over the palpated fibrotic band. Expose and isolate the entire muscle and tendon length with sharp dissection. Resect the entire affected muscle to increase joint range of motion.

SUTURE MATERIALS AND SPECIAL INSTRUMENTS

Self-retaining retractors and a periosteal elevator assist tissue retraction and reflection.

POSTOPERATIVE CARE

Postoperative physical rehabilitation is critical if significant fibrosis and contracture are to be prevented. Rehabilitation includes passive range of motion, stretching, and aquatherapy (see Chapter 11). Use of a temporary cast to maintain limb extension for 8 to 12 hours per day may help in some animals.

PROGNOSIS

The prognosis for gracilis or semitendinosus myopathy is guarded, with recurrence of fibrosis and restriction of gait occurring within

4 months in most dogs. Intensive, long-term physical rehabilitation following surgical intervention may improve the prognosis.

SUPERFICIAL DIGITAL FLEXOR TENDON DISPLACEMENT

DEFINITION

Superficial digital flexor tendon displacement (SDFD) occurs when the tendon slides off the calcaneus. The displacement causes lameness of the affected limb.

GENERAL CONSIDERATIONS AND CLINICALLY RELEVANT PATHOPHYSIOLOGY

The superficial digital flexor tendon is the most superficial part of the Achilles tendon and inserts distally on the toes. Tearing of the retinaculum that keeps the tendon over the tuber calcanei allows the tendon to displace medially or laterally. Lateral displacement is more common than medial displacement.[7] Dysplasia of the tuber calcanei leading to a shallow groove may contribute to tendon displacement.

DIAGNOSIS

Clinical Presentation

Signalment

SDFD is rare in dogs and has been reported in one cat. Shelties may be overrepresented for SDFD. No age or size predisposition is known.

History

History may include insidious or acute onset of rear limb lameness.

Physical Examination Findings

Dogs with SDFD have hindlimb lameness and swelling of the tip of the calcaneus. In most cases, it is possible to feel the tendon slide off the tip of the calcaneus (Videos 35.6, 35.7, and 35.8).

Diagnostic Imaging

Radiography is typically not helpful. Ultrasound examination is not necessary for diagnosis but may demonstrate intermittent displacement of the tendon.

Laboratory Findings

Consistent laboratory abnormalities are not present.

DIFFERENTIAL DIAGNOSIS

The diagnosis of SDFD can usually be made from historical and physical examination findings. Injuries of the common calcanean tendon must be differentiated from this condition.

MEDICAL MANAGEMENT

Medical management, including the use of nonsteroidal analgesics, is generally not effective for treatment of SDFD.

Physical Rehabilitation

Physical rehabilitation alone is not successful in the management of SDFD; it should be combined with surgery.

SURGICAL TREATMENT

Surgery involves reduction of the displaced tendon and imbrication of the torn retinaculum.

Preoperative Management

These animals are otherwise generally healthy, and minimal preoperative care is necessary.

Anesthesia

See p. 976 for anesthetic management of animals with orthopedic disease.

Surgical Anatomy

The superficial digital flexor tendon is the most superficial part of the common calcanean tendon. It passes over the tuber calcanei with a bursa between the bone and the flat tendon. A retinaculum holds the tendon in place over the calcaneus.

Positioning

Clip the rear limb from the mid tibia to the foot, and position the animal in sternal recumbency with the affected limb extended over the end of the table.

SURGICAL TECHNIQUE

Incise the skin directly over or slightly medial or lateral to the calcaneus. Expose the superficial digital flexor tendon and the retinaculum. In chronic cases, the retinaculum may be difficult to clearly identify or differentiate from the tendon. *Resect excessive retinacular tissue. Reduce the tendon to its normal position, and suture the retinaculum to hold the tendon in place using simple interrupted nonabsorbable sutures. Close the wound routinely.*

SUTURE MATERIALS AND SPECIAL INSTRUMENTS

Self-retaining retractors assist tissue retraction and reflection.

POSTOPERATIVE CARE

Postoperatively, place the limb in a soft padded bandage with or without a light splint. Maintain the bandage for 1 to 2 weeks. Limit activity for the first 2 weeks; follow this with leash walking for 4 weeks and then a gradual return to normal activity.

PROGNOSIS

The prognosis for SDFD is excellent, and most animals return to normal activity within 2 months.

36 Other Diseases of Bones and Joints

PANOSTEITIS

DEFINITION

Panosteitis is a disease of young dogs that causes lameness, bone pain, endosteal bone production, and occasionally subperiosteal bone production. Synonyms include *enostosis, eosinophilic panosteitis, juvenile osteomyelitis,* and *osteomyelitis of young German shepherds*.

GENERAL CONSIDERATIONS AND CLINICALLY RELEVANT PATHOPHYSIOLOGY

Panosteitis is an idiopathic entity causing endosteal and periosteal new bone formation. Osseous compartment syndrome due to a protein-rich, high-calorie diet has been proposed as a potential cause. Excessive protein may cause intraosseous edema and secondary increased medullary pressure and ischemia. Although some periosteal new bone is often evident, the predominant change is endosteal bone formation as the marrow is invaded by bone trabeculae. The marrow remains highly cellular with varying degrees of fibrosis, and no evidence of chronic inflammation, acute infection, or malignancy is noted.

DIAGNOSIS

Clinical Presentation

Signalment

Panosteitis predominantly affects male, large-breed dogs. Young dogs (<2 years of age) are most commonly affected; however, older dogs have occasionally been diagnosed with it. German shepherds have a higher risk of developing this disease than other large-breed dogs.

History

The hallmark of panosteitis is shifting leg lameness associated with pain on deep bone palpation. Although initial episodes of panosteitis may present as acute lameness in a single limb, the typical history consists of chronic, intermittent, shifting leg lameness.

Physical Examination

Affected dogs are commonly lame in only a single limb. Firm palpation of affected long bones usually elicits pain.

Diagnostic Imaging

Radiographic signs of panosteitis are progressive. Radiographs of affected limbs are often normal during early stages, and clinical signs may precede radiographic abnormalities by up to 10 days. If clinical signs are consistent with panosteitis but radiographs are normal, radiographs should be repeated in 7 to 10 days. Nuclear scintigraphy is a more sensitive diagnostic test of panosteitis than radiography. The earliest radiographic signs include widening of the nutrient foramen and blurring and accentuation of trabecular patterns (which are often difficult to identify, except in retrospect); these are followed by the appearance of radiopaque, patchy, or mottled bone within medullary canals (Fig. 36.1). Eventually, remodeling of medullary canals occurs, and cortical thickening may remain as the only residual finding.

Laboratory Findings

Consistent laboratory abnormalities are not present.

DIFFERENTIAL DIAGNOSIS

Panosteitis must be differentiated from other orthopedic diseases of large, immature dogs (e.g., osteochondritis dissecans, fragmented coronoid process, ununited anconeal process in forelimbs; hip dysplasia, osteochondritis dissecans of rear limbs). When radiographic evidence of panosteitis and other orthopedic diseases is present concurrently, panosteitis is usually assumed to be causing the acute clinical signs.

> **NOTE** Panosteitis has the best prognosis of all juvenile orthopedic diseases.

MEDICAL MANAGEMENT

The disease is self-limiting; treatment consists of controlling pain. Nonsteroidal antiinflammatory drugs (see Table 34.3) are usually administered during acute episodes of lameness. Exercise restriction is recommended when the animal is lame. Owners should be warned of the likelihood of recurrence, but the long-term prognosis is excellent for complete recovery.

SURGICAL TREATMENT

Surgical treatment of panosteitis is not indicated.

PROGNOSIS

The disease is self-limiting, and most animals eventually have normal function of affected limbs without evidence of pain. However, the disease may continue to affect different limbs,

ABSTRACT

Several common disease processes affect the musculoskeletal system that are not categorized within trauma or degeneration. Many of these diseases affect young dogs, and it is important that veterinarians be able to recognize and treat them.

KEYWORDS

panosteitis
hypertrophic osteodystrophy
hypertrophic osteopathy
craniomandibular osteopathy
osteosarcoma

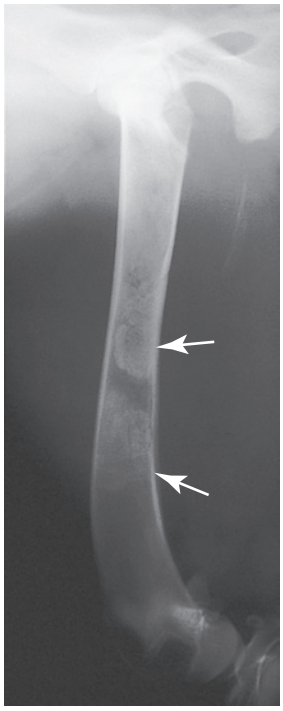

FIG. 36.1 Lateral radiograph of the femur of an immature dog with panosteitis. Note the areas of increased opacity within the medullary canal *(arrows)*.

causing pain and lameness until the dog reaches maturity. Clinical signs rarely persist after maturity.

NOTE Advise owners that panosteitis may recur, but that it usually resolves by the time the dog is 2 years of age.

HYPERTROPHIC OSTEODYSTROPHY

DEFINITION

Hypertrophic osteodystrophy (HOD) is a disease that causes disruption of metaphyseal trabeculae in long bones of young, rapidly growing dogs. Synonyms include *skeletal scurvy, canine scurvy, Moeller-Barlow disease, osteodystrophy types I and II, metaphyseal osteopathy*, and *metaphyseal dysplasia.*

GENERAL CONSIDERATIONS AND CLINICALLY RELEVANT PATHOPHYSIOLOGY

The cause of HOD is unknown. Proposed causative factors include vitamin C deficiency, oversupplementation of dietary calcium, and infectious organisms. A link to canine distemper virus has been postulated but is not supported by epidemiologic studies. Experimentally, vaccination protocols have been associated with the development of HOD in Weimaraner puppies; however, no specific vaccine has been identified. The pathogenesis is obscure, but an apparent disturbance of metaphyseal blood supply leads to changes in the physis and adjacent metaphyseal bone, causing delayed ossification of the physeal hypertrophic zone. The acute phase lasts approximately 7 to 10 days. Affected animals show signs ranging from mild lameness to anorexia, pyrexia, lethargy, severe lameness, refusal to rise, and generalized weight loss. Clinical signs may wax and wane.

NOTE Affected animals may be very ill, requiring intense supportive care.

Grossly, the metaphyseal regions of long bones are widened with perimetaphyseal soft tissue swelling. A line of separation of metaphyseal trabeculae is present parallel to the growth plate. Histologic microfractures of trabeculae are evident and are surrounded by inflammatory cells and necrosis. Failure of bone deposition on the calcified cartilage lattice of metaphyseal bone is evident.

DIAGNOSIS

Clinical Presentation

Signalment

This disease affects young, rapidly growing, large-breed dogs, and males are affected more often than females. Clinical signs are usually first noted at 3 to 4 months of age; however, they may occur as early as 2 months. Relapses may occur as late as 8 months of age. The highest incidence is in the fall. Weimaraners may be at increased risk.

History

An acute onset of lameness is often reported, and puppies may be so severely affected that they refuse to walk. Inappetence and lethargy are commonly reported by owners. A history of recent diarrhea may precede the onset of lameness.

Physical Examination Findings

Findings on physical examination range from mild lameness to severe lameness affecting all four limbs. More severely affected animals are often unable to stand or walk. Long bone metaphyses are swollen, warm, and painful on palpation. Swelling is often present in all four limbs; however, forelimb swelling may be more obvious, especially in distal radial metaphyses. Severely affected dogs may be depressed, anorexic, and pyrexic (body temperature of up to 106°F [41°C]).

Diagnostic Imaging

Radiographs of affected long bones reveal an irregular radiolucent zone in the metaphysis, parallel and proximal to the physis. This gives the appearance of a double physeal line. Metaphyseal flaring with increased bone opacity occurs because of periosteal proliferation in later stages of the disease. This reaction subsides with time but may leave a permanently widened metaphysis (Fig. 36.2).

Laboratory Findings

Laboratory abnormalities are not usually found. Hypocalcemia has been noted in a few affected dogs, but its significance is unknown. Bacteremia has rarely been reported in association with HOD.

DIFFERENTIAL DIAGNOSIS

This condition should be differentiated from septic arthritis, septic physitis, and panosteitis.

FIG. 36.2 Radiograph of the distal radius and ulna of a dog with hypertrophic osteodystrophy. A parallel lucency *(arrowheads)* proximal and adjacent to the physis is typical of this disease.

MEDICAL MANAGEMENT

Analgesics should be administered to control pain (see Tables 13.2 and 34.3). Occasionally, severely debilitated animals require fluid support. Glucocorticoids, antibiotics, and vitamin C have been administered to affected dogs but have not proved effective in shortening the course or severity of the disease. Bacterial infection should be ruled out before glucocorticoids are administered.

PROGNOSIS

Most animals recover fully within 7 to 10 days of the onset of clinical signs; however, multiple relapses may occur. Occasionally, severe debilitation or multiple, severe relapses cause owners to request that affected animals be euthanized. Interference with normal physeal development may cause permanent deformity of long bones.

NOTE Warn owners that multiple relapses may occur and that deformity of the long bones may occur.

HYPERTROPHIC OSTEOPATHY

DEFINITION

Hypertrophic osteopathy (HO) is a diffuse periosteal reaction resulting in new bone formation around the metacarpal, metatarsal, and long bones. Synonyms include *pulmonary osteoarthropathy, hypertrophic pulmonary osteoarthropathy,* and *hypertrophic pulmonary osteopathy.*

GENERAL CONSIDERATIONS AND CLINICALLY RELEVANT PATHOPHYSIOLOGY

HO can affect all four limbs. It can be a paraneoplastic syndrome (e.g., primary and metastatic lung tumors, esophageal carcinoma, rhabdomyosarcoma of the bladder, anal sac adenocarcinoma, renal transitional cell carcinoma, nephroblastoma), or it may be associated with other diseases (e.g., granulomatous lesions, chronic megaesophagus, patent ductus arteriosus, bacterial endocarditis, heartworm disease). The precise pathophysiology of this disease is unknown. Alterations in pulmonary function have been suggested to increase peripheral blood flow, resulting in connective tissue congestion. The increased peripheral blood flow is thought to be neurally mediated. The periosteum responds by forming new bone on the cortical surfaces of the metacarpal, metatarsal, and long bones. This new bone may be diffuse or nodular. Histologically, the affected area is made of bands of new cortical bone that contain small, fibrous marrow spaces.

DIAGNOSIS

Clinical Presentation

Signalment

Any breed or size of dog may be affected; however, because it is most commonly associated with neoplasia, HO is usually seen in older animals. This condition has rarely been reported in cats.

History

Dogs are usually brought in because of lethargy, reluctance to move, and swelling of the distal extremities. Onset of clinical signs may be acute or gradual.

Physical Examination Findings

Affected limbs are warm and swollen. Because this condition occurs secondary to diseases elsewhere in the body, an effort should be made to identify the underlying causative factors. A thorough physical examination is essential when evaluating affected animals.

Diagnostic Imaging

Radiographs of the limbs reveal a uniform periosteal proliferation, which is seen initially on the phalanges and metacarpal and metatarsal bones (Fig. 36.3). As the disease progresses, periosteal proliferation progresses proximally (i.e., radius/ulna and tibia/fibula). Articular surfaces of long bones are usually spared and appear normal.

Thoracic radiographs are used to identify any underlying pulmonary or mediastinal disease (e.g., primary or metastatic neoplasia, granulomatous lesions, heartworm disease). Abdominal ultrasonography should be performed to identify underlying abdominal disease if thoracic disease is not identified. Advanced imaging modalities (computed tomography [CT], magnetic resonance imaging) may be necessary in some cases to identify the primary lesion.

Laboratory Findings

Results of laboratory analysis usually reflect the underlying disease. Thrombocytosis may occur in some dogs; however, the cause is poorly understood.

FIG. 36.3 Dorsopalmar view of the forepaw of a dog with hypertrophic osteopathy. Note the periosteal proliferation on the abaxial surfaces of the metacarpal bones and radius and ulna *(arrows)*. Note that the carpal joints are spared.

DIFFERENTIAL DIAGNOSIS

This condition should be differentiated from bone neoplasia.

MEDICAL MANAGEMENT

Treatment is aimed at the underlying disease process. Remission of periosteal proliferation may occur after resolution or resection of the primary lesion.

PROGNOSIS

The prognosis depends on the possibility for complete resolution of the underlying disease process. If the primary disease can be resolved, the secondary HO often resolves. Although clinical signs often disappear within 1 to 2 weeks after treatment, bone lesions may take months to remodel.

CRANIOMANDIBULAR OSTEOPATHY

DEFINITION

Craniomandibular osteopathy *(mandibular periostitis, lion's jaw)* is a proliferative bone disease of immature dogs involving the occipital bones, tympanic bullae, and mandibular rami.

GENERAL CONSIDERATIONS AND CLINICALLY RELEVANT PATHOPHYSIOLOGY

The cause of craniomandibular osteopathy is unknown. It is most often recognized in West Highland white terriers, Cairn terriers, and Scottish terriers. A genetic predisposition is suspected in many breeds; in West Highland white terriers, it is thought to have an autosomal recessive inheritance pattern. A similar syndrome (calvarial hyperostotic syndrome) has been reported in bullmastiffs. Craniomandibular osteopathy has been associated with canine leukocyte adhesion deficiency in Irish setters. A link to canine distemper virus has been postulated but is not supported by epidemiologic studies.

Proliferation of new, coarse, trabecular bone occurs adjacent to the mandibular rami, occipital bones, and tympanic bullae in affected animals. This new bone formation causes irregular enlargement of mandibles and tympanic bullae. Existing lamellar bone is resorbed by osteoclasis and is replaced with new bone that expands beyond the periosteal borders. Osteoclastic destruction of the original lamellar bone is accompanied by invasion of inflammatory cells (i.e., neutrophils, lymphocytes, and plasma cells). Normal bone marrow is lost as it is replaced with a vascular fibrous stroma. This proliferative stage of disease occurs when the dog is approximately 5 to 7 months old and is accompanied by intermittent fever, discomfort when eating, and pain when the mouth is forced open. Owners should be warned that multiple relapses may occur; however, bone proliferation decreases as dogs reach maturity and physes close.

DIAGNOSIS

Clinical Presentation

Signalment

Although young West Highland white terriers, Cairn terriers, and Scottish terriers are most commonly affected, this disease has been sporadically reported in other breeds. Clinical signs are usually first noted when the dog is 3 to 8 months of age. Males and females are equally affected. No seasonal distribution has been noted. Calvarial hyperostosis syndrome has typically been considered to be a disease of bullmastiffs.

History

Owners often note that the animal is reluctant to eat, drools, and has trouble chewing food. Pain is often evident when the mouth is opened.

Physical Examination Findings

Affected dogs have bilaterally enlarged mandibles and tympanic bullae. In severe cases, fusion of these structures may occur, preventing the jaws from being fully opened. Pain on opening of the mouth and intermittent fever (body temperature reading of up to 104°F [40°C] for 3–4 days) may be observed.

Diagnostic Imaging

Skull radiographs typically reveal increased irregular bone density of the caudal mandibles; in many dogs the tympanic bullae also appear denser (Fig. 36.4). Whereas approximately one-third of dogs have lesions confined to the mandibles, some animals also have lesions of the base of the skull and/or have a thickened calvarium. As dogs reach maturity, the edges of the new bone become smooth and affected areas shrink.

Laboratory Findings

Specific laboratory abnormalities are not seen. Blood cultures are negative.

DIFFERENTIAL DIAGNOSIS

Craniomandibular osteopathy must be differentiated from infection (i.e., abscesses or osteomyelitis) and primary bone neoplasia.

FIG. 36.4 Lateral radiograph of the skull of a dog with craniomandibular osteopathy. Note the areas of periosteal proliferation.

MEDICAL MANAGEMENT

Analgesics (see Table 34.3) should be given to control pain until the animal reaches maturity. Severely debilitated animals that cannot open their mouths enough to eat solid foods require oral fluid nourishment or a feeding tube. Although antibiotics and glucocorticoids are often administered during febrile episodes, they will not alter disease progression.

SURGICAL TREATMENT

Surgical therapy is not indicated. Surgical resection of bone bridging the mandible and tympanic bullae in dogs with severely restricted jaw motion has been unsuccessful; however, rostral mandibulectomy (see p. 336) may allow the dog to lap gruel. Affected dogs should not be used for breeding purposes.

PROGNOSIS

The prognosis is guarded until the extent of bone production is known (i.e., at maturity). Excessive bone production, leading to fusion of mandibular and tympanic bullae, can restrict mandibular motion sufficiently to prevent dogs from eating. These animals are often euthanized.

NOTE Warn owners that multiple relapses may occur until maturity.

BONE NEOPLASIA

DEFINITIONS

Primary bone neoplasia arises from cells located within the bone structure. **Metastatic bone tumors** are those that spread to bone from other primary locations. Primary and metastatic tumors may occur in the **appendicular skeleton** (i.e., long bones) or the **axial skeleton** (skull, vertebrae, ribs, and pelvis).

GENERAL CONSIDERATIONS AND CLINICALLY RELEVANT PATHOPHYSIOLOGY

Primary bone tumors of dogs and cats include osteosarcoma, chondrosarcoma, fibrosarcoma, hemangiosarcoma, giant cell tumor, liposarcoma, periosteal osteosarcoma, periosteal fibrosarcoma, parosteal osteosarcoma, osteoma, multilobular osteoma, multilobular chondroma, osteochondroma, and chondroma (Tables 36.1 and 36.2). Primary tumors of the appendicular skeleton of dogs most commonly arise in the distal radial metaphysis, proximal humerus, proximal or distal femur, and proximal or distal tibia. Benign bone tumors (e.g., osteoma, ossifying fibroma, multilobular osteomas and chondromas, osteochondromas, enchondromas, chondromas) are generally slow growing. Multiple cartilaginous exostosis (MCE, or osteochondromatosis) is a histologically benign disease of cats that occurs after skeletal maturity, in contrast to dogs, in which the disease occurs before growth plate closure (see Table 36.2). Depending on tumor accessibility, complete surgical excision of benign bone tumors is usually curative.

Osteosarcoma is the most common malignant bone tumor in dogs, occurring most often in the metaphyseal region of long bones of large or giant breed dogs.[1–3] Common sites include distal aspect of the radius, proximal aspect of the humerus, distal aspect of the femur, proximal and distal aspect of the tibia, and distal aspect of or diaphyseal region of the ulna.[1–4] In dogs less than 15 kg, tumors are most commonly located in the humerus and femur.[5] A genetic cause of osteosarcoma appears likely based on experimental and clinical studies. Osteosarcoma has been associated with fractures and metallic implants and may also occur within radiation fields following radiation treatment of soft tissue sarcomas.

Osteosarcoma is a locally aggressive tumor, causing bone lysis and/or production. Metastasis is common and usually occurs early in the course of disease. Although fewer than 15% of affected dogs have radiographically detectable thoracic metastases at presentation, 90% die or are euthanized within 1 year of diagnosis because of complications associated with pulmonary metastasis.[4,6] Improved chances for survival are possible with amputation (see p. 1303) or limb-sparing procedures (see p. 1305) combined with chemotherapy.

NOTE Warn owners that despite the fact that there may not be evidence of metastasis at the time of diagnosis, metastases are typically noted within a year.

Osteosarcoma is the most common tumor of the axial skeleton. Common sites include the mandible, maxilla, spine, cranium, ribs, nasal cavity and paranasal sinuses, and pelvis. Because it is the most commonly diagnosed bone tumor of dogs, it is used as the model for evaluation, diagnosis, treatment, and prognosis of bone tumors in this chapter. Although the workup needed to diagnose neoplasia is similar for all bone tumors, treatment and prognosis vary depending on tumor type (see Tables 36.1 and 36.2).

Histologically, osteosarcoma is composed of anaplastic mesenchymal cells that produce osteoid. Histologic subgroups include osteoblastic, fibroblastic, chondroblastic, osteoclastic, poorly

TABLE 36.1 Malignant Bone Neoplasia in Dogs

Tumor	Incidence	Metastasis	Treatment	Prognosis
Osteosarcoma of the appendicular skeleton	~75% of all bone tumors	High rate of early metastasis to lungs and soft tissue; bone metastasis is a late complication	• Amputation and chemotherapy with carboplatin and/or doxorubicin • Limb sparing in selected cases • Palliative radiation therapy for painful bone lesions	Mean survival time with amputation alone is 12–20 wk, median survival time with limb sparing or amputation plus carboplatin and doxorubicin is approximately 300–400 d
Osteosarcoma of the axial skeleton	Less common than appendicular tumors	Highly metastatic, local recurrence except for mandible, which is slower to metastasize	• Local resection of tumor (i.e., mandible and rib) • Carboplatin, local radiation as adjunct to surgery to reduce local recurrence	Median survival time is ~22 wk, 1-y survival is ~25%, rate of tumor recurrence is ~67%
Fibrosarcoma	<5% of bone tumors	Slower to metastasize than osteosarcoma	• Amputation (doxorubicin may prove beneficial for metastatic disease) • Limb sparing in select cases	Poor prognosis (but complete excision of low-grade tumors without metastases may be curative)
Chondrosarcoma	5%–10% of bone tumors	Slow to metastasize	Amputation (chemotherapy not of proven benefit)	May be good after amputation or resection of lesion
Hemangiosarcoma	<5% of bone tumors	May be multicentric, often involves spleen and right atrium, highly metastatic	• Amputation (chemotherapy not of proven benefit) • Limb sparing in select cases	Poor prognosis because of multiple organ involvement, mean survival time <5 mo
Giant cell tumor	Rare	Metastasis to lymph nodes, lung, and bones	Amputation	Poor prognosis
Liposarcoma	Rare	Metastasis to lung, liver, and lymph nodes	Amputation or local resection	Poor prognosis
Fracture-associated sarcoma	Uncommon, associated with fractures in which healing has been complicated; represents 5% of osteosarcomas	Metastasis occurs in ~15% of cases	• Amputation • Limb-sparing techniques • Chemotherapy	Same as osteosarcoma

TABLE 36.2 Malignant Bone Neoplasia in Cats

Tumor	Incidence	Metastasis	Treatment	Prognosis
Osteosarcoma	Most common primary bone tumor in cats (70%–80%)	Metastasis is uncommon	Amputation, radiation therapy, or excision of skull tumors	Median survival time is 12–50 mo; 12 mo median survival with appendicular osteosarcoma
Fibrosarcoma	Rare, often due to secondary invasion of bone from soft tissue	Incidence is unknown	Amputation	Long disease-free intervals reported (e.g., 10–18 mo)
Chondrosarcoma	4% of bone tumors, reported in the scapula	Incidence is unknown	Amputation	Prognosis guarded
Squamous cell carcinoma	Local bone invasion, occurs in oral cavity, orbit, and digits	See section on oral tumors	Amputation, mandibulectomy, maxillectomy, ± radiation therapy; see section on oral tumors	See section on oral tumors
Multiple cartilaginous exostosis (osteochondromatosis)	Uncommon, usually feline leukemia virus (FeLV) positive, benign physeal lesion in dogs	Multiple sites common; scapula, vertebra, mandible in cats, physeal in dogs	Palliative removal of painful lesions	Guarded in cats (favorable in dogs)

differentiated, and telangiectatic osteosarcoma. An inflammatory component is often present in fracture-associated sarcoma (i.e., a sarcoma that arises in the diaphysis of a long bone at the site of a previous fracture), reflecting altered healing patterns and chronic inflammation associated with these tumors.

Osteosarcoma accounts for the majority of primary bone tumors in cats (approximately 70%–80%). Osteosarcoma occurs more commonly in the hindlimbs of cats and may have a lower rate of metastasis than in dogs. Cats rarely have evidence of metastasis at presentation.

DIAGNOSIS

Clinical Presentation

Signalment

Large- and giant-breed dogs have the greatest incidence of appendicular bone neoplasia. The median age of dogs with osteosarcoma is 7 years; however, a small, early peak is seen in dogs 18 to 24 months of age.[2–4] Large size is a greater determinant of risk than breed, although greyhounds, Rottweilers, and Great Danes have been shown to be at increased risk. Males may be slightly more commonly affected than females. Primary bone tumors of the axial skeleton are more common than appendicular tumors in small breed dogs[5]; the median age of affected animals is 8 to 9 years. The mean age of osteosarcoma in cats is 8 to 10 years. No apparent breed or sex predilection has been identified in either species for tumors of the axial skeleton.

History

Dogs with primary bone neoplasia affecting the appendicular skeleton are usually examined for lameness and/or localized limb swelling. Pathologic fracture may cause acute, severe lameness. Dogs with primary bone tumors of the axial skeleton usually have pain, reluctance to walk, and visible swelling. Clinical signs may be acute or chronic and progressive. Signs of axial bone neoplasia depend on the location. Neoplasia of the skull may cause difficulty eating and visible swelling, whereas neoplasia of the spine may lead to pain or neurologic deficits.

Primary bone neoplasia in cats may cause deformity and lameness. MCE may result in pain and rapidly progressive swelling. Common sites for MCE include the spine, scapula, and mandible.

Physical Examination Findings

Dogs with appendicular tumors are often lame. The limb may be enlarged and firm. Systemic signs of illness (e.g., fever, anorexia, weight loss) are uncommon in acute stages of the disease. Tumors of the axial skeleton are often palpable as firm swellings. Tumors affecting the vertebral column may cause acute signs of lameness or paralysis. Respiratory abnormalities associated with pulmonary metastasis are rare until late in the disease. Cats with primary appendicular bone neoplasia exhibit lameness and painful firm swelling. Cats with axial neoplasia may exhibit difficulty eating, neurologic deficits, and firm painful swelling.

NOTE Lameness is often the first sign of appendicular bone tumors.

Diagnostic Imaging

Radiographs of affected bones and the thorax should be evaluated. Radiographic signs of osteosarcoma include cortical and trabecular bone lysis, periosteal bone proliferation, and soft tissue swelling (Fig. 36.5). Thoracic radiographs should include a dorsoventral or ventrodorsal view and both lateral recumbent views (i.e., right and left lateral views). These radiographs should be carefully evaluated for evidence of tumor metastasis. Alternatively, contrast-enhanced CT of the thorax can replace survey radiographs; CT is more sensitive than radiography in detecting small metastatic lesions.[4] Although radiographic signs associated with primary bone neoplasia cannot be differentiated from those associated with fungal osteomyelitis, coupling radiographic signs with signalment and history can help determine whether neoplasia should be considered likely. Ultimately, histopathology is necessary for confirmation. If limb-sparing surgery is being considered, magnetic resonance imaging should be used to determine the extent of the disease.

FIG. 36.5 Radiographs of a distal radius of a dog with osteosarcoma. Note the cortical lysis, periosteal proliferation, and soft tissue swelling.

Bone scintigraphy may help identify multifocal bone lesions in dogs with neoplasia. Osteosarcoma rarely affects multiple bones; however, metastatic lesions have been identified on scintigraphy at initial diagnosis. Scintigraphy may also be indicated when other forms of cancer (i.e., multiple myeloma and metastatic bone cancer) are suspected.

NOTE Three-view thoracic radiography or contrast-enhanced CT is essential in evaluating for pulmonary or thoracic wall metastases.

Laboratory Findings

No laboratory abnormalities are consistently found with primary or metastatic bone neoplasia. Fine-needle aspiration and cytology may be suggestive of bone neoplasia in a large percentage of cases. Ultrasound guidance may aid in identifying areas of bone lysis, enabling easier aspiration. Cytology of fine-needle aspirates may provide adequate evidence of primary bone tumor to allow initiation of treatment; however, definitive diagnosis of bone neoplasia usually necessitates histologic evaluation of samples obtained by biopsy or excision. Successful identification of a tumor requires obtaining adequate tissue samples and a pathologist with expertise in interpreting bone samples. Multiple samples should be obtained to increase diagnostic accuracy. Closed trephine (see p. 1302) or Jamshidi bone biopsy (11-gauge × 10 cm; Cardinal Health) from the center of the radiographic lesion is more accurate than biopsy of transitional zones between tumor and normal bone. The latter biopsies are commonly interpreted as reactive bone. Using fluoroscopy or other advanced imaging techniques to choose the biopsy site increases the chances of optimal, diagnostic biopsies. Alternatively, radiographs obtained after biopsy can be used to confirm biopsy location. Biopsies should be obtained in such a way that potentially seeded tumor cells will be removed during subsequent surgery.

Staging

Systemic staging is critical for proper decision making in animals with skeletal neoplasia. Thoracic radiography or CT is indicated.

Pulmonary nodules must be 6 to 8 mm in diameter to be detected by radiography; CT is more sensitive in the detection of pulmonary disease (see Chapter 14). Bone survey radiography sometimes detects secondary skeletal sites, although this is not routinely performed. Bone scintigraphy may be performed, although it is not readily available and reports on its usefulness are conflicting. Spread to regional lymph nodes is rare, and fine-needle aspiration is not indicated unless an enlarged lymph node is recognized clinically.

DIFFERENTIAL DIAGNOSIS

Suspected primary neoplastic lesions must be differentiated from bacterial osteomyelitis, fungal osteomyelitis, metastatic bone tumor (e.g., prostatic carcinoma), direct extension of soft tissue tumors (e.g., nail bed carcinomas), hypertrophic pulmonary osteopathy, bone infarcts, hypervitaminosis A, periosteal response to trauma, and aneurysmal bone cysts.

MEDICAL MANAGEMENT

Most dogs with skeletal neoplasia ultimately die from metastatic disease, thus extensive research has explored the benefits of chemotherapy to treat micrometastasis. Multiple-modality treatment (e.g., amputation and chemotherapy) has extended the life span of dogs with osteosarcoma.[1,3,6] Numerous protocols are available for administering one or a combination of these drugs. In cases in which tumor resection is impossible, palliative radiation treatment may diminish pain. Readers are referred to an oncology text for additional information regarding medical treatment of osteosarcoma.

SURGICAL TREATMENT

Treatment of appendicular bone tumors involves limb amputation, scapulectomy, acetabulectomy, hemipelvectomy (see p. 1303), or tumor resection combined with limb salvage techniques and chemotherapy (see p. 1305).[1,3,7–9] Limb-sparing techniques are challenging surgical procedures and should be performed only by experienced surgeons with advanced training. Maxillary and mandibular tumors are treated by mandibulectomy (see p. 336) or maxillectomy (see p. 335), plus appropriate chemotherapy or radiation therapy. Spinal tumors can occasionally be treated with en bloc resection, but the procedure is difficult. Tumors of the ribs are treated with en bloc resection.

NOTE Perform fine-needle aspiration or another biopsy technique before amputating a leg because fungal and neoplastic lesions can be radiographically indistinguishable.

NOTE Dogs with severe concurrent orthopedic or neurologic disease may have difficulty ambulating after amputation; they should be evaluated carefully before amputation.

Preoperative Management

A thorough physical examination should be performed to identify concurrent problems that might interfere with anesthesia. Limb amputation involves loss of large quantities of tissue, fluid, electrolytes, and red blood cells. Animals should be well hydrated before surgery, and adequate fluids should be administered during surgery. Broad-spectrum antibiotics should be administered perioperatively, particularly during mandibulectomy, maxillectomy, and limb-sparing techniques (see Chapter 9).

NOTE Perioperative fluid management is essential during limb amputation owing to the large fluid loss associated with the surgery.

Anesthesia

Bone aspirates may be performed under sedation; bone biopsy usually requires general anesthesia. Patients undergoing bone biopsy, amputation, or limb sparing are usually middle-aged to older, and appropriate preanesthetic diagnostics (chemistry panel, complete blood count, thoracic radiographs) should be performed (see p. 976 for suggested anesthetic protocols). In patients undergoing forelimb amputation or limb sparing, analgesia may be provided via a brachial plexus block (see p. 152). Patients undergoing hindlimb amputation should receive an epidural (see p. 153). Patients undergoing midfemoral hindlimb amputation should receive a femoral-sciatic nerve block (see p. 153). Amputation of a front limb or a hindlimb should include direct nerve blocks before nerve transection (see p. 151).

Surgical Anatomy

Surgical anatomy varies with tumor location. Refer to the appropriate bone for an anatomic description.

Positioning

For bone biopsy, forelimb amputation, rear leg amputation, and limb sparing, the animal is usually positioned in lateral recumbency with the affected leg uppermost. A wide area around the proposed biopsy site is clipped and prepped for aseptic surgery. For the other procedures, the leg is prepped from the dorsal and ventral midline to the foot.

SURGICAL TECHNIQUE

Bone Biopsy

A Michele trephine or a Jamshidi bone marrow biopsy needle can be used to obtain a bone biopsy. Michele trephines obtain a larger sample of bone; however, risk of fracture through the biopsy site may be increased (Box 36.1). Jamshidi needles secure a smaller sample that may decrease the risk of pathologic fracture after biopsy. Accurate diagnoses can be obtained with either technique in more than 80% of cases.

NOTE If limb sparing is a goal, take care in locating the biopsy tract in an area that can be easily removed with surgical resection of the tumor. If possible, the same surgeon should perform the biopsy and the limb-sparing procedure (see Video 36.1).

If appropriate, locate the optimal site for biopsy by examining the leg under fluoroscopy while inserting a hypodermic needle into the skin to mark the spot. Once the desired spot for biopsy has been located, make a small skin incision (Video 36.1). For large lesions, make the incision over the center of the lesion. Locate the skin incision so that the biopsy tract that may be seeded with tumor cells during the biopsy can be removed during the definitive treatment

BOX 36.1 Important Considerations for Bone Biopsy

- Obtain samples from the radiographic center of tumors.
- Obtain multiple samples.
- Take radiographs after biopsy to confirm biopsy site.
- Using Jamshidi needles may reduce the risk of pathologic fracture.
- Have pathologists with expertise in evaluating bone biopsies perform histology.

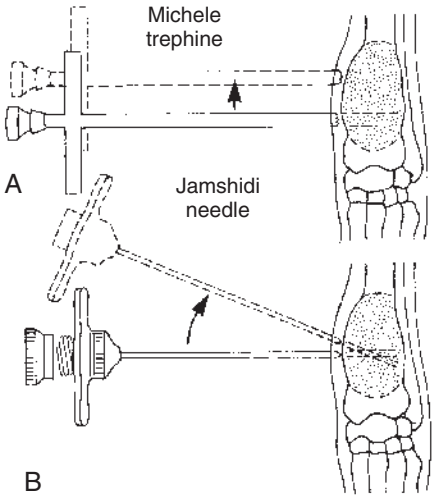

FIG. 36.6 Bone biopsy may be performed with (A) a Michele trephine or (B) a Jamshidi needle.

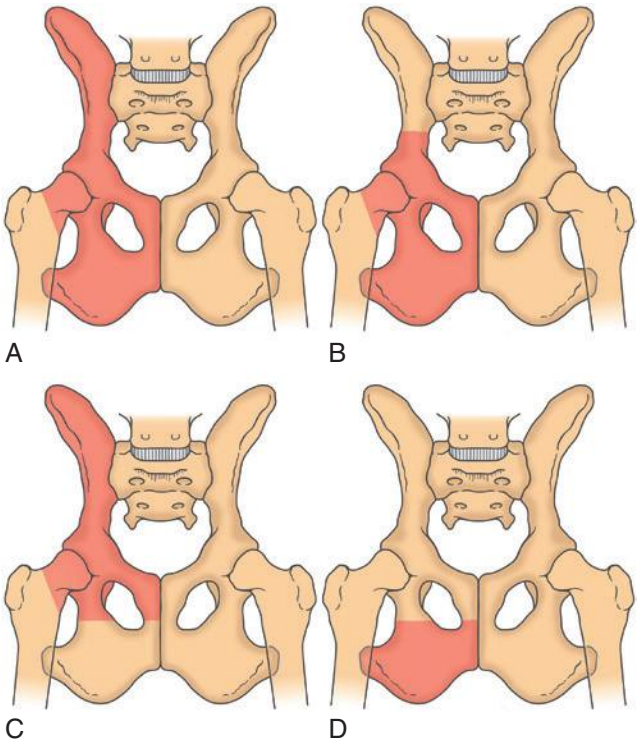

FIG. 36.7 Hemipelvectomy categories. (A) Total hemipelvectomy. (B) Mid-to-caudal partial hemipelvectomy. (C) Mid-to-cranial partial hemipelvectomy. (D) Caudal partial hemipelvectomy.

procedure (position the biopsy tract so that it does not interfere with skin flaps developed to cover the amputated bone end, should amputation be necessary). Push the trephine or the needle through soft tissue to the bone cortex. Remove the stylet, and advance the trephine or cannula through the bone by rotating the instrument back and forth. Once the biopsy instrument has been well seated, gently rock the instrument back and forth to separate the biopsy sample from surrounding bone. Remove the cannula and push the specimen out by inserting the probe into the front opening. Repeat the procedure to obtain multiple specimens (Fig. 36.6).

Amputation

Forelimb amputation may be performed by removing the scapula, or, alternatively, the limb can be removed by disarticulation at the shoulder joint. Scapular removal (forequarter amputation) is often preferred because muscular atrophy around the scapular spine is eliminated.

When tumors affect the femur, the coxofemoral joint should be disarticulated and the entire femur removed. Tumors involving the coxofemoral joint or pelvis require an acetabulectomy or hemipelvectomy. Four variations of hemipelvectomy have been described: total hemipelvectomy (Fig. 36.7A), mid-to-caudal partial hemipelvectomy (Fig. 36.7B), mid-to-cranial partial hemipelvectomy (Fig. 36.7C), and caudal partial hemipelvectomy (Fig. 36.7D).[7,9]

After amputation, the entire tumor should be resubmitted for histologic evaluation to confirm the diagnosis.

Forequarter Amputation

Make a skin incision from the dorsal border of the scapula, over the scapular spine, to the proximal third of the humerus. Continue the skin incision around the forelimb at this level (Fig. 36.8A). Transect the trapezius and omotransversarius muscles at their insertions on the scapular spine. Transect the rhomboideus muscle from its attachment on the dorsal border of the scapula, and retract the scapula laterally to expose its medial surface (Fig. 36.8B). Next, elevate the serratus ventralis muscle from the medial surface of the scapula (Fig. 36.8C). Continue to retract the scapula to expose the brachial plexus and axillary artery and vein. Ligate the axillary artery and vein with a three-clamp and transfixation suture technique (Fig. 36.9). Transect the brachial plexus. Transect the brachiocephalicus muscle, deep and superficial pectoral muscles, and latissimus dorsi muscle near their humeral insertions (Fig. 36.8D–E). Remove the forelimb. To close the wound, approximate the muscle bellies to cover the brachial plexus and vessels, and then suture subcutaneous tissue and skin (Fig. 36.8F).

Coxofemoral Disarticulation

Make a skin incision around the rear limb at the level of the middle third of the femur (Fig. 36.10A). The lateral aspect of the skin incision should extend farther distally than the medial aspect. *On the medial side, open the femoral triangle by incising between the pectineus muscle and the caudal belly of the sartorius muscle to expose and ligate the femoral artery and vein (Fig. 36.10B) using a three-clamp technique. Transect the sartorius, pectineus, gracilis, and adductor muscles approximately 2 cm from the inguinal crease (Fig. 36.10C). Isolate the medial circumflex femoral vessels over the iliopsoas muscle and ligate them. Transect the iliopsoas muscle*

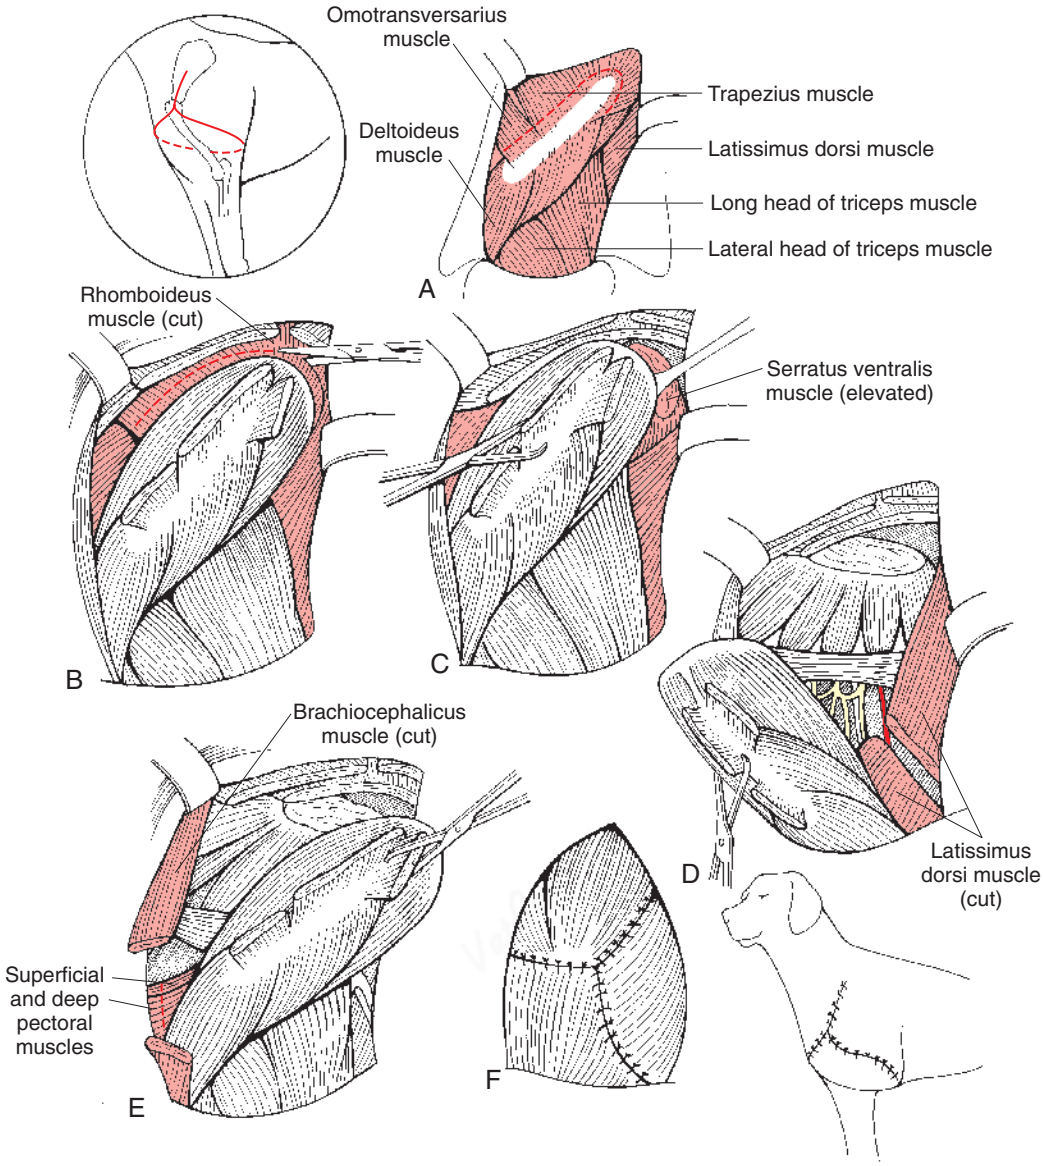

FIG. 36.8 (A) For forequarter amputation, make a skin incision from the dorsal border of the scapula, over the scapular spine, to the proximal third of the humerus. Continue the skin incision around the forelimb at this level. Transect the trapezius and omotransversarius muscles at their insertions on the scapular spine. (B) Transect the rhomboideus muscle from its attachment on the dorsal border of the scapula. (C) Elevate the serratus ventralis muscle from the medial surface of the scapula. (D) Retract the scapula laterally to expose the axillary artery and vein for ligation. Transect the brachial plexus. Transect the latissimus dorsi muscle near its humeral insertion. (E) Transect the brachiocephalicus and deep and superficial pectoral muscles near their humeral insertions, and remove the forelimb. (F) To close the wound, approximate the muscle bellies to cover the brachial plexus and vessels and suture subcutaneous tissue and skin.

at its insertion on the lesser trochanter, and reflect it cranially to expose the joint capsule (Fig. 36.10D). Incise the joint capsule and cut the ligament of the head of the femur (Fig. 36.10E). On the lateral side, transect the biceps femoris muscle and the tensor fascia lata at the midfemoral level, and reflect them proximally to expose the greater trochanter and sciatic nerve (Fig. 36.10F). Sever the sciatic nerve distal to its muscular branches to the semimembranosus, semitendinosus, and biceps femoris muscles. Transect the gluteal muscle insertions close to the greater trochanter (Fig. 36.10G). Transect the semimembranosus and semitendinosus muscles at the level of the proximal third of the femur. Sever the external rotator muscles and the quadratus femoris muscle at their attachments around the trochanteric fossa. Elevate the rectus femoris muscle from its origin on the pelvis. Incise the joint capsule circumferentially and remove the limb. Close the wound by flapping the biceps femoris muscle medially and suturing it to the gracilis and semitendinosus muscles. Flap the tensor fascia lata caudally, and suture it to the sartorius muscle. Suture subcutaneous tissue and skin.

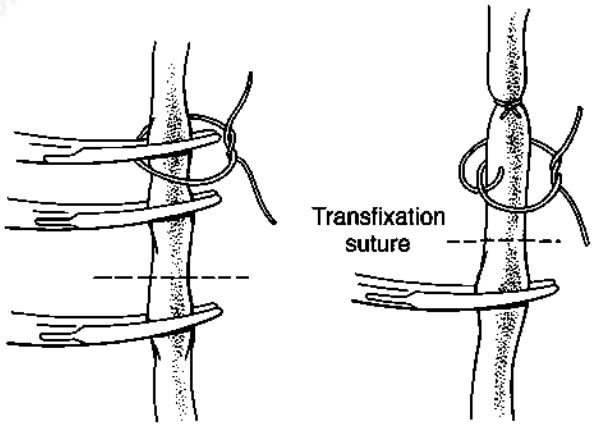

FIG. 36.9 A three-forceps and transfixation suture technique. Place three forceps on the artery and ligate it in the crushed area of the proximal forceps. Place a transfixation ligature distal to the first ligation, and cut the vessel between the middle and distal clamps.

Midfemoral Amputation

Make a skin incision around the rear limb at the level of the distal third of the femur (Fig. 36.11A). The lateral aspect of the skin incision should extend farther distally than the medial aspect. On the medial side, transect the gracilis muscle and the caudal belly of the sartorius at the midfemoral level (Fig. 36.11B). Isolate and ligate the femoral vessels (see Fig. 36.9). Transect the pectineus muscle through its musculotendinous junction (Fig. 36.11C). Transect the cranial belly of the sartorius muscle. Transect the quadriceps muscle proximally to the patella (Fig. 36.11D). Transect the biceps femoris muscle at the same level as the quadriceps muscle. Isolate and cut the sciatic nerve at the level of the third trochanter. Transect the caudal muscles, including the semimembranosus, semitendinosus, and adductor muscles at the midfemoral level (Fig. 36.11E). Elevate the insertion of the adductor muscle from the linea aspera of the femur (Fig. 36.11F). Cut the femur at the junction of the proximal and middle thirds of the diaphysis, and remove the limb. Close the wound by flapping the quadriceps muscle caudally to cover the femoral stump and suturing it to the adductor muscle. Flap the biceps muscle medially, and suture it to the gracilis and semitendinosus muscles. Muscles should be apposed to completely protect the distal end of the femur. *Suture subcutaneous tissue and skin.*

Acetabulectomy

Make a skin incision around the rear limb at the level of the middle third of the femur (see Fig. 36.10A). Extend the lateral aspect of the skin incision farther distally than the medial aspect. On the medial side, open the femoral triangle by incising between the pectineus muscle and the caudal belly of the sartorius muscle to expose and ligate the femoral artery and vein (see Fig. 36.10B) using a three-clamp technique. Transect the sartorius, pectineus, gracilis, and adductor muscles approximately 2 cm from the inguinal crease (see Fig. 36.10C). Isolate the medial circumflex femoral vessels over the iliopsoas muscle, and ligate them. Transect the iliopsoas muscle at its insertion on the lesser trochanter, and reflect it cranially to expose the joint capsule (see Fig. 36.10D). Incise the joint capsule and cut the ligament of the head of the femur (see Fig. 36.10E). On the lateral side, transect the biceps femoris muscle and the tensor fascia lata at the midfemoral level, and reflect them proximally to expose the greater trochanter and sciatic nerve (see Fig. 36.10F). Sever the sciatic nerve distal to its muscular branches to the semimembranosus, semitendinosus, and biceps femoris muscles. Transect the gluteal muscle insertions close to the greater trochanter (see Fig. 36.10G). Transect the semimembranosus and semitendinosus muscles at the level of the proximal third of the femur. Sever the external rotator muscles and the quadratus femoris muscle at their attachments around the trochanteric fossa. Elevate the rectus femoris muscle from its origin on the pelvis. Using a sagittal saw, cut through the ilial shaft, ischium, and pubis to remove the acetabulum and limb. Close the wound by flapping the biceps femoris muscle medially and suturing it to the gracilis and semitendinosus muscles. Flap the tensor fascia lata caudally, and suture it to the sartorius muscle. Suture subcutaneous tissue and skin.

Limb-Sparing Techniques

Some dogs with preexisting orthopedic and neurologic disease do not ambulate adequately after amputation. Additionally, some owners will not permit amputation. Limb-sparing techniques that involve en bloc resection of the tumor and replacement with a bone or metal substitute can be used in selected cases. Numerous limb-sparing techniques (e.g., cortical allograft, cortical allograft with polymethylmethacrylate, cortical ulnar autograft with microvascular transfer, rollover cortical ulnar autograft, intraoperative radiation, bone transport, stainless steel prosthetic bone substitute) have been described. The most suitable candidates for limb sparing are dogs with osteosarcoma of the distal radius that affects less than 50% of the bone. Limb sparing is considered an advanced surgical technique and should be performed only by experienced surgeons with specific training in the procedure.

Cortical Allograft with Carpal Arthrodesis

AP *Position the dog in lateral recumbency. Dissect around the pseudocapsule of the tumor. Osteotomize the bone 3 to 5 cm proximal to the radiographic margin of the tumor. Take a biopsy specimen from the proximal margin of resection to check for tumor. Transect the extensor carpi radialis muscle and remove it with the tumor, along with any other muscles or tendons that are involved.* The distal margin of resection is the joint surface.

Incise the joint capsule, and dissect the tumor free. Remove the articular cartilage of the carpal bones in preparation for carpal arthrodesis. Replace the resected bone with a cortical allograft stabilized with a long, dynamic compression plate (see p. 993). Filling the graft with polymethylmethacrylate decreases the incidence of implant loosening and allograft fracture, but controversial results have been reported regarding possible delays in graft incorporation. *Make sure that the plate is of sufficient length that at least four screws can be positioned in the proximal radius and three positioned distal to the graft. Harvest autogenous cancellous bone (or harvest the graft before dissecting the tumor to prevent contamination of the donor site), and place it at the host-graft interface and at the arthrodesis site (Fig. 36.12). If desired, insert a closed suction drain adjacent to the graft before closing the wound. Close subcutaneous tissue and skin routinely.*

SUTURE MATERIALS AND SPECIAL INSTRUMENTS

A Michele trephine or a Jamshidi needle is needed for a bone biopsy. An osteotome and mallet, oscillating saw, or Gigli wire is used to sever the bone when a midhumeral or midfemoral amputation is performed. Nonabsorbable (polypropylene or

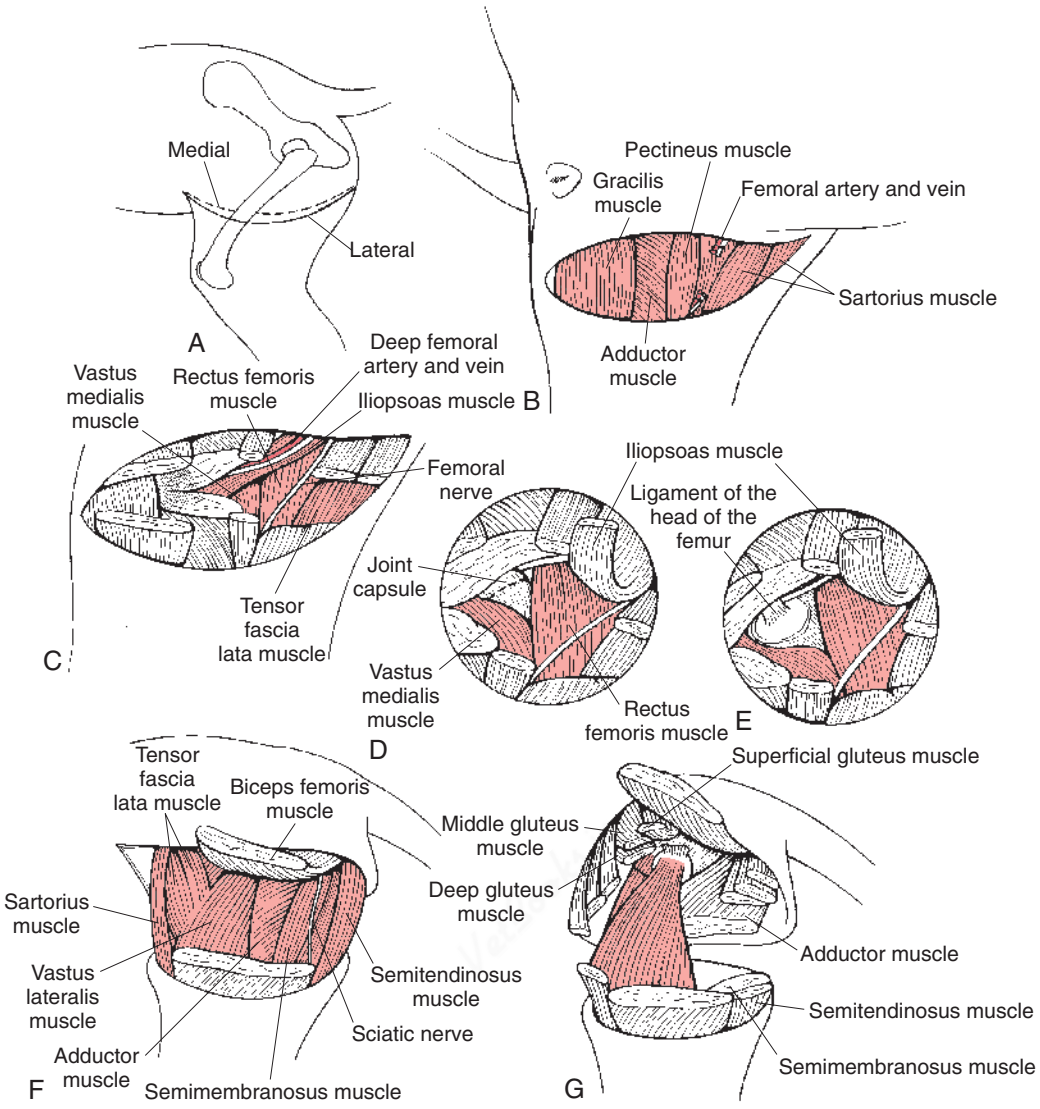

FIG. 36.10 (A) For coxofemoral disarticulation, make a skin incision around the rear limb at the level of the middle third of the femur. (B) On the medial side, open the femoral triangle by incising between the pectineus muscle and the caudal belly of the sartorius muscle to expose and ligate the deep femoral artery and vein. (C) Transect the sartorius, pectineus, gracilis, and adductor muscles approximately 2 cm from the inguinal crease. (D–E) Transect the iliopsoas muscle at its insertion on the lesser trochanter, and reflect it cranially to expose the joint capsule. Incise the joint capsule and cut the ligament of the head of the femur. (F) On the lateral side, transect the biceps femoris muscle and the tensor fascia lata at the midfemoral level. (G) Sever the sciatic nerve distal to its muscular branches to the semimembranosus, semitendinosus, and biceps femoris muscles. Transect the gluteal muscle insertions close to the greater trochanter. Transect the semimembranosus and semitendinosus muscles at the level of the proximal third of the femur. Sever the external rotator muscles and the quadratus femoris muscle at their attachments around the trochanteric fossa. Elevate the rectus femoris muscle from its origin on the pelvis. Remove the limb.

nylon) or strong synthetic absorbable (polydioxanone or polyglyconate) suture should be used for vessel ligation during amputation. Plating equipment and an allograft are needed for limb sparing.

POSTOPERATIVE CARE AND ASSESSMENT

Postoperative care after biopsy is minimal, but most dogs are in pain after the biopsy, probably because of subperiosteal hemorrhage. Pressure bandages may be needed if bleeding is excessive. After amputation, the surgical site should be observed for swelling, redness, and/or discharge. If hemorrhage or seroma formation is noted, pressure may be applied to the surgical site by applying a circumferential bandage around the thorax or pelvis. Cryotherapy aids in decreasing inflammation and pain. Mobility should be encouraged after surgery so that the animal can learn to walk on three legs; however, some animals require initial support to prevent falling, especially on slick surfaces. Most

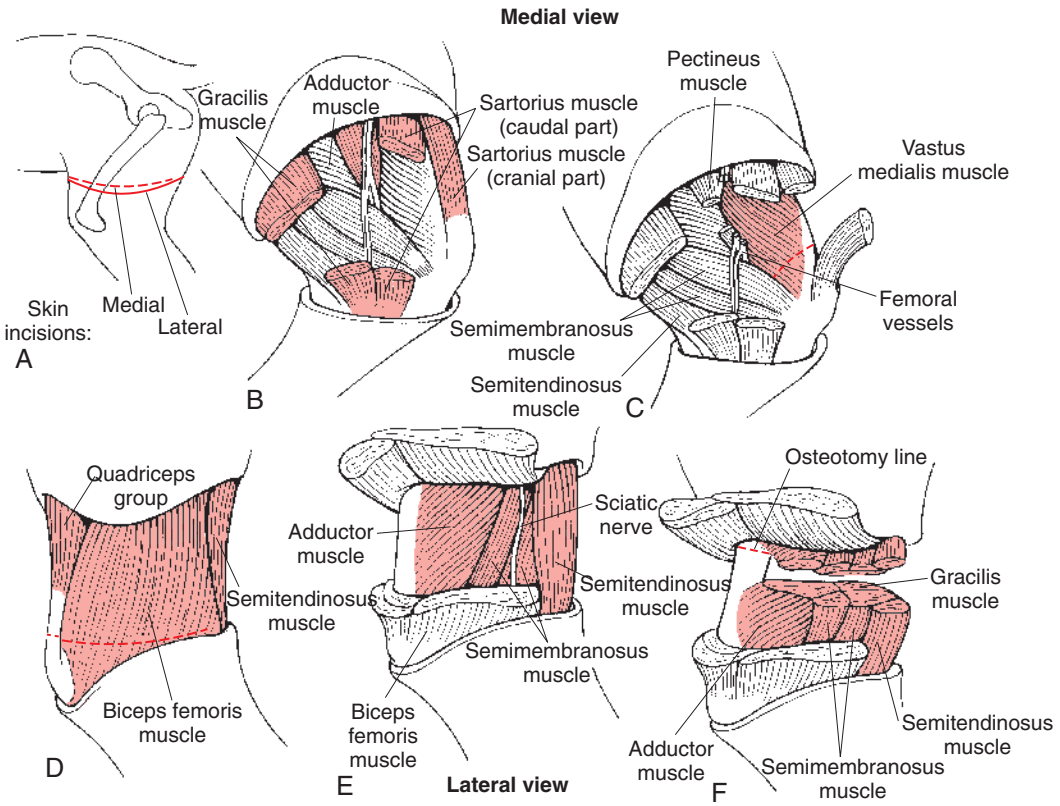

FIG. 36.11 (A) For midfemoral amputation, make a skin incision around the rear limb at the level of the distal third of the femur. (B) On the medial side, transect the gracilis muscle and the caudal belly of the sartorius at the midfemoral level. (C) Isolate and ligate the femoral vessels. Transect the pectineus muscle through its musculotendinous junction. Transect the cranial belly of the sartorius muscle. (D) Transect the quadriceps muscle proximally to the patella. (E) Transect the biceps femoris muscle at the same level as the quadriceps muscle. Isolate and cut the sciatic nerve at the level of the third trochanter. Transect the semimembranosus, semitendinosus, and adductor muscles at midfemoral level. (F) Elevate the insertion of the adductor muscle from the linea aspera of the femur. Cut the femur at the junction of the proximal and middle thirds of the diaphysis and remove the limb.

animals learn to ambulate on three limbs within 4 weeks (many by 1 week after surgery); however, some dogs may require coaxing and encouragement. Pain relief is often evident after amputation of limbs with large neoplastic lesions. Potential complications of amputation include seroma formation, bleeding, infection, and suture line dehiscence.

NOTE Many owners are reluctant to accept amputation and must be advised of the animal's ability to adapt to walking on three legs. Keeping a video of a dog with an amputation to show owners considering this procedure may be helpful (Video 36.2).

Postoperative care after limb sparing includes care of the closed suction drainage system (if used) and removal of the drain when drainage subsides (usually 1 day after surgery). The leg should be supported in a padded bandage to control postoperative swelling. The incision must be protected from self-mutilation with bandages and/or an Elizabethan collar. Decreased exercise is recommended for 3 to 4 weeks; however, controlled exercise or physical therapy may be necessary to prevent flexure contracture of the digits. Analgesics should be continued postoperatively for 10 to 14 days (see Tables 13.2 and 34.3).

PROGNOSIS

Dogs with appendicular osteosarcoma have a poor prognosis owing to the aggressive biological behavior of this tumor. Some factors that have been found to negatively influence prognosis include age, histologic grade, and lymph node metastases.[2] The overall median survival time from the time of diagnosis for dogs undergoing amputation alone is 5 months, but adjuvant chemotherapy may increase the overall median survival time to approximately 1 year.[2] Euthanasia is typically requested by owners when pulmonary metastases cause depression, anorexia, and/or respiratory distress.

Limb-sparing procedures in conjunction with chemotherapy generally results in good or adequate limb function in most dogs. Median survival times with limb sparing have been reported to be compatible to amputation when combined with adjunct chemotherapy.[3] Complications associated with traditional limb sparing vary dramatically according to the study cited and include local tumor recurrence, implant complications, and infection.

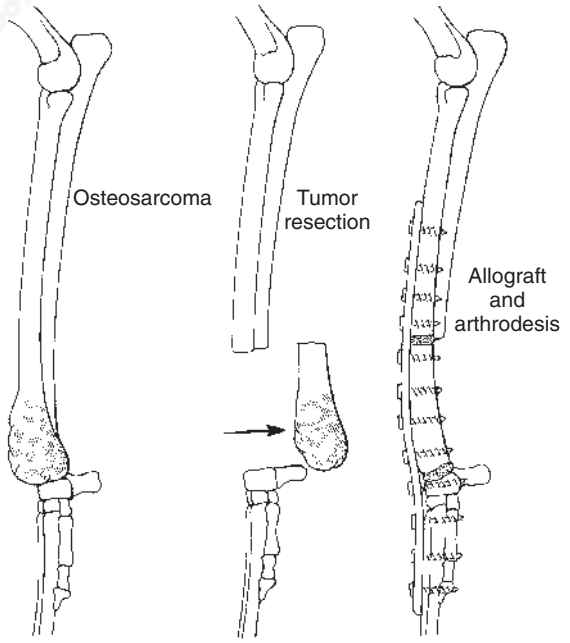

FIG. 36.12 A limb-sparing procedure for distal radial osteosarcoma. Resect the affected bone and soft tissue. Replace the bone with a cortical allograft, and stabilize it with a compression plate. Perform an arthrodesis of the carpus concurrently.

Interestingly, improved survival has been noted in dogs treated with limb sparing when the surgical site became infected.

In contrast to osteosarcoma, dogs with appendicular chondrosarcoma can be treated effectively with amputation alone. Survival time is significantly associated with histologic grade.

Cats with appendicular osteosarcoma often survive for 2 years or longer after amputation. Adjuvant chemotherapy has not been effective in the management of osteosarcoma in cats. The prognosis for cats diagnosed with MCE is poor based on the tendency of these lesions to recur following surgical excision.

JOINT NEOPLASIA

DEFINITIONS

Primary joint neoplasms are tumors that arise from synovial linings of diarthrodial joints, tendon sheaths, and/or bursae. The tumors of practical importance are those arising from synovioblastic tissue, called **synovial sarcomas** *(malignant synovioma, synovial cell sarcoma),* **histiocytic sarcomas,** and **synovial myxomas**.

GENERAL CONSIDERATIONS AND CLINICALLY RELEVANT PATHOPHYSIOLOGY

Synovial cell sarcomas are rare tumors arising from synovioblastic mesenchyme in deep connective tissue around joints. Histiocytic sarcomas likely arise from macrophage/monocyte cell lines. Synovial myxomas arise from fibroblasts in myxomatous tissue. Joints above the carpus and tarsus are more commonly affected than distal joints. The biological behavior of these tumors ranges from slow growth to aggressive invasion of adjacent tissue. Metastasis to regional lymph nodes, lungs, bone, and other locations may occur.

DIAGNOSIS

Clinical Presentation

Signalment

Synovial sarcomas occur most commonly in large, middle-aged dogs; however, a breed predisposition has not been identified. Bernese mountain dogs, flat-coated retrievers, and golden retrievers may be affected more commonly with histiocytic sarcomas.

History

Affected dogs and cats are usually lame. A mass near a joint may occasionally be noticed by owners. Masses may grow slowly for a period; rapid growth may then occur.

Physical Examination Findings

Masses vary in size but are usually firm with some fluctuant areas. The degree of lameness appears to correlate with the amount of bone involvement.

Diagnostic Imaging

Radiographs of involved joints are needed to evaluate the extent of bone and soft tissue involvement. Lobulated soft tissue masses may be present in the joint region. Bone changes (e.g., lysis of subchondral bone and cortex, new bone production) are often noted on either side of the joint (Fig. 36.13). This contrasts with the appearance of primary bone tumors, which seldom appear to affect the bones on either side of the joint or to "cross a joint." Thoracic radiographs or contrast-enhanced CT should be performed to evaluate for the presence of pulmonary metastasis.

Laboratory Findings

Consistent laboratory abnormalities are not present.

DIFFERENTIAL DIAGNOSIS

Neoplastic joint lesions must be differentiated from synovial cysts, which are well-circumscribed masses attached to the joint capsule, tendon sheath, or bursa. Synovial cell sarcomas must be differentiated from cruciate disease, fungal and infectious joint diseases (e.g., septic arthritis, erosive arthritis, villonodular synovitis), and other tumors (e.g., fibrosarcoma, rhabdomyosarcoma, liposarcoma, hemangiopericytoma, malignant fibrous histiocytomas, giant cell tumors of soft tissue, primary bone tumors). A definitive diagnosis requires a biopsy of the lesion; however, excisional biopsy (limb amputation) rather than incisional biopsy may be warranted if massive bone destruction precludes therapy other than amputation. Fine-needle aspiration can reveal malignant cells but will not allow visualization of tumor architecture necessary for definitive diagnosis of tumor type in many cases.

SURGICAL TREATMENT

Amputation is the recommended treatment for these tumors (see p. 1303). Local excision is not recommended because of the high recurrence rate. Concurrent chemotherapy may be beneficial.

POSTOPERATIVE CARE AND ASSESSMENT

See p. 1306 for recommendations regarding the postoperative care of animals after amputation. Periodic examination of affected

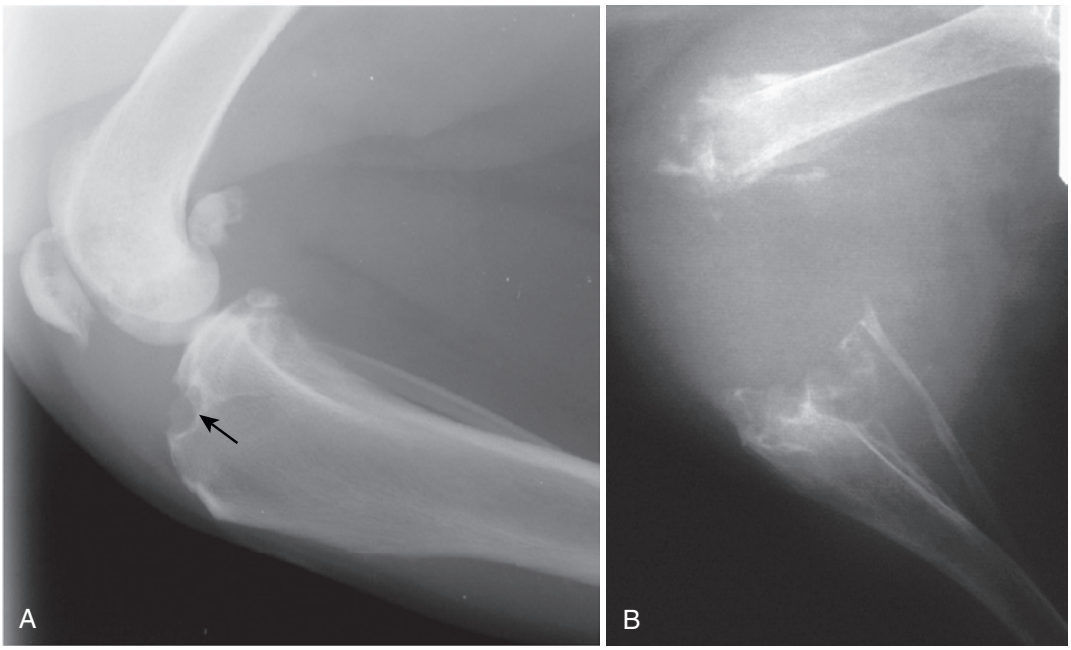

FIG. 36.13 Lateral radiograph of a dog with synovial cell sarcoma of the stifle joint. Note the (A) subtle lysis of the proximal tibia *(arrow)* and soft tissue opacity in the stifle and (B) extensive lysis of the distal femur and proximal tibia. Because both sides of the joint are affected, a soft tissue tumor should be suspected.

animals is recommended for early detection of local recurrence or metastasis.

PROGNOSIS

The prognosis varies with type of tumor. Although these tumors have historically been considered to be slow-growing tumors that metastasize late in the course of disease, a 2010 study suggested that metastasis is common after amputation.[10] The average survival time for dogs with synovial cell sarcoma is 32 months, 5 months with histiocytic sarcoma, and 30 months with synovial myxoma.[10,11] Histiocytic sarcoma has the highest rate of metastasis, whereas synovial myxoma has the lowest. Dogs undergoing surgical tumor excision or amputation have a significantly higher survivability than those receiving no treatment.

OSTEOMYELITIS

DEFINITIONS

Osteomyelitis is an inflammation of bone, although most commonly the term is used to describe inflammation due to infection. Acute **osteomyelitis** is characterized by systemic illness, pain, and soft tissue swelling without visible radiographic alterations in bone. **Chronic osteomyelitis** exists when acute and systemic clinical signs have subsided, but infection manifested by draining sinuses, recurrent cellulitis, abscess formation, and progressive destructive and proliferative osseous changes is present. A **sequestrum** is a piece of devitalized bone that has become separated from surrounding tissue. **Glycocalyx** (biofilm) is a combination of bacterial slime and host cellular debris that shrouds bacterial colonies and facilitates bacterial adhesion.

GENERAL CONSIDERATIONS AND CLINICALLY RELEVANT PATHOPHYSIOLOGY

Most bone infections in dogs and cats are bacterial in origin. Many of these are monomicrobial infections with β-lactamase–producing *Staphylococcus pseudintermedius* predominating. Polymicrobial infections also occur and may harbor mixtures of *Streptococcus* spp., *Proteus* spp., *Escherichia coli, Klebsiella* spp., and *Pseudomonas* spp. Anaerobic bacteria are an important cause of osteomyelitis; they are present in more than two-thirds of bone infections. Anaerobes may exist alone as the sole causative agent, or more commonly as single organisms in polymicrobial infection. Anaerobes isolated from bone infections include *Actinomyces* spp., *Clostridium* spp., *Peptostreptococcus* spp., *Bacteroides* spp., and *Fusobacterium* spp. Characteristics of anaerobic infections include fetid odor, sequestration of bone fragments, and evidence of bacteria with differing morphology on gram-stained smears.

NOTE Treatment failure may result from lack of identification and inappropriate treatment of anaerobic bacteria.

Bacterial osteomyelitis is often classified as hematogenous or posttraumatic; however, the former is rarely reported in dogs. Fracture-associated osteomyelitis has been reported to occur most commonly in the radius/ulna and femur. Bone is normally resistant to infection; thus predisposing factors are required for osteomyelitis to occur. Factors associated with osteomyelitis include bone necrosis or sequestration, fracture instability, ischemia, implants or other foreign materials, and alteration of the systemic or local immune response. A common source of bacterial inoculation is surgical site contamination during open

fracture reduction. Although the type and quantity of bacteria inoculated are important factors in the development of bone infection, bacteria alone do not necessarily cause osteomyelitis. Other important factors in the pathogenesis of posttraumatic osteomyelitis are (1) extent of soft tissue damage and alteration of blood supply, (2) formation of a biofilm (glycocalyx), and (3) stability of fracture repair. Tissue damage may be caused by the injury or may occur during the surgical procedure. Damaged soft tissue and devitalized bone serve as excellent culture media for bacteria. Bacterial proliferation is also potentiated by foreign materials in the wound (e.g., synthetic suture materials or implants). Glycocalyx is a combination of bacterial slime and host cellular debris that shrouds bacterial colonies and facilitates bacterial adhesion. The biofilm also protects bacteria from phagocytosis, host antibodies, and antibiotic effectiveness. Osteomyelitis is worsened by fracture instability. Continual motion impairs revascularization of spaces between fractured bone ends, which in turn prevents host defense mechanisms from protecting the area.

Mycotic bone infections are acquired through hematogenous dissemination of inhaled spores. Offending organisms are endemic in some geographic locations and include *Blastomyces dermatitidis, Coccidioides immitis,* and, less commonly, *Histoplasma capsulatum, Cryptococcus neoformans,* and *Aspergillus* spp. Although viral osteomyelitis is considered uncommon, newer evidence suggests that some canine bone diseases may be viral in origin. Sequences of ribonucleic acid (RNA) homologous with canine distemper viral RNA have been detected in osteoblasts of dogs with metaphyseal osteopathy (HO). Other causes of osteomyelitis include parasites, foreign bodies, and corrosion of metallic implants. Diagnosis of osteomyelitis is often suspected on the basis of history, clinical signs, and radiographic findings.

DIAGNOSIS

Clinical Presentation

Signalment

Any age, breed, or sex of dog or cat may be affected.

History

Historic findings may include recent open reduction and stabilization of a fracture, bite wounds, open traumatic wounds, or habitation in an endemic fungal region; however, fungal osteomyelitis must never be eliminated simply because the patient does not live in an endemic area.

Physical Examination Findings

Clinical features of osteomyelitis vary depending on the stage of the disease. The initial response of bone to infection is inflammation; soft tissue in the area can become hot, reddened, swollen, and painful (Fig. 36.14). The animal is often pyrexic, depressed, and partially or totally anorexic. Distinguishing between acute osteomyelitis and inflammation associated with surgical intervention is frequently difficult. Persistence of an elevated temperature for longer than 48 hours postoperatively or a neutrophilic left shift increases the likelihood that infection is present rather than just surgically induced trauma. However, lack of either of these findings does not exclude infection. Animals with chronic osteomyelitis are usually brought in for evaluation of draining tracts and/or lameness. Pyrexia, anorexia, and other clinical signs associated with systemic disease are frequently lacking.

FIG. 36.14 A dog with femoral osteomyelitis. Note the draining tract on the caudolateral aspect of the thigh.

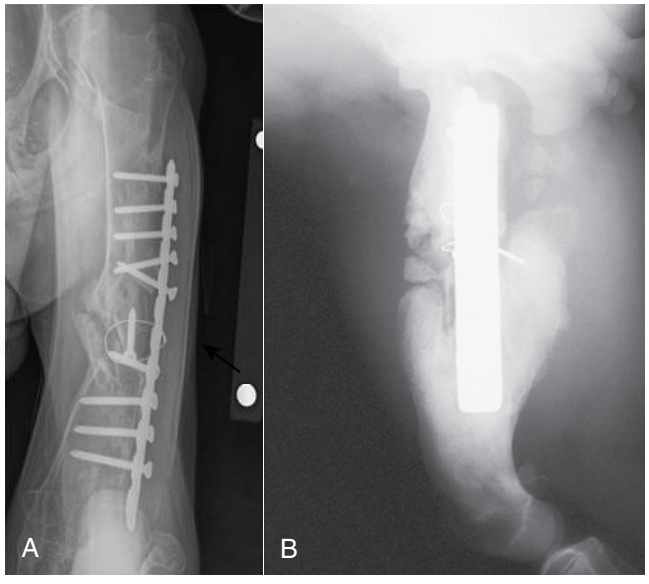

FIG. 36.15 Radiograph of a dog with (A) acute and (B) chronic osteomyelitis following open reduction and stabilization of a femoral fracture with cerclage wires. Extensive periosteal reaction and sequestrum formation are present.

Diagnostic Imaging

Specific radiographic findings vary depending on the stage of disease, site of infection, and pathogenicity of infective organisms. Soft tissue swelling is the first sign of acute osteomyelitis and may be observed as early as 24 hours postinfection. Radiographic signs may lag behind the clinical presentation. Early radiographic changes include periosteal proliferation with deposition of new bone in a lamellar pattern oriented perpendicular to the long axis of the bone. Lamellated periosteal reactions are typically associated with osteomyelitis, whereas solid periosteal new bone formation is not typically associated with infection (Fig. 36.15). As the infection progresses, lysis of the medullary cavity becomes apparent. Sequestra may develop if bone has been devitalized, and sclerosis and lysis become interspersed throughout cortical and medullary bone at the site of infection as *involucra* (new bone formation around a sequestrum) form. Sequestered bone appears more radiographically opaque than surrounding bone.

Laboratory Findings

With acute osteomyelitis, systemic evidence of infection is often present, which is typically indicated by an elevated white blood cell count and neutrophilia with or without a left shift. Laboratory analysis in dogs with chronic osteomyelitis is usually normal.

Microbiological culturing is definitive for bacterial osteomyelitis and is essential in determining the organism's in vitro susceptibility to antimicrobial drugs. Sample specimens for culture should not be collected from draining tracts. Organisms cultured from draining tracts correlate with pathogens isolated at surgery in fewer than half of patients. Preferably, aerobic and anaerobic cultures should be obtained from bone collected during surgical intervention. Alternatively, collection of culture samples via fine-needle aspiration of material directly surrounding the involved bones may sometimes be useful if adequate material is obtained for culture. Fungal cultures and cytologic or histologic evaluation of biopsies may be diagnostic of fungal osteomyelitis. Serology may be helpful in diagnosing blastomycosis and coccidioidomycosis. Cryptococcosis is best diagnosed by detecting antigenemia. Urine excretion of antigens may diagnose blastomycosis and histoplasmosis. Fungal hyphae may often be found in urine sediment cytology in dogs with systemic aspergillosis, and there is an enzyme-linked immunosorbent assay or ELISA for *Aspergillus antigenemia* that appears useful. Serology for antibodies against histoplasmosis or systemic aspergillosis is of dubious sensitivity and specificity.

NOTE Collect samples for bacterial culture from deep fine-needle aspirates. Do not culture draining tracts.

DIFFERENTIAL DIAGNOSIS

Osteomyelitis must be differentiated from bone neoplasia. Radiographic changes of osteomyelitis are similar to those following surgery in which periosteal trauma has been excessive. Hematogenous metaphyseal osteomyelitis must be differentiated from HOD.

MEDICAL MANAGEMENT

Medical management consisting of antibiotic therapy and application of warm packs may be effective in patients with hematogenous osteomyelitis or in those with postoperative osteomyelitis, although infection can rarely be cleared as long as implants remain in place. Medical therapy is reasonable when the affected area exhibits signs of inflammation, but sequestra, necrotic tissue, or pockets of exudate make medical therapy unlikely to be successful by itself. Additionally, if the patient has postoperative osteomyelitis, implant and bone stability must be present for medical management to be effective. After bone healing, implant removal is usually necessary to resolve the infection. Appropriate antibiotic therapy is determined by culture and sensitivity and is continued for a period of at least 28 days.

SURGICAL TREATMENT

If sequestra or pockets of exudate are present, drainage and debridement of necrotic tissue are necessary. The fracture must be stable, and appropriate antimicrobial therapy should be instituted on the basis of culture and susceptibility testing. Treatment of chronic osteomyelitis entails maintenance or provision of fracture stability, removal of loose implants and sequestered bone, cancellous bone grafting of bony deficits, and appropriate antimicrobial therapy. Implanted bactericidal carriers (polymethylmethacrylate or a biodegradable polymer) have been used extensively in humans and in horses, but their use in small animals has been limited.

Preoperative Management

In patients with acute osteomyelitis, antibiotic therapy should be initiated immediately with bactericidal agents that have a broad spectrum of activity against aerobic and anaerobic bacteria (e.g., clindamycin plus enrofloxacin). Definitive antimicrobial therapy is determined through culture and susceptibility testing. Antimicrobial therapy of animals with chronic osteomyelitis should be based on culture and sensitivity testing of the offending organisms at surgery. Perioperative antibiotics should not be administered to these patients until intraoperative cultures have been obtained.

Anesthesia

Most animals with osteomyelitis are otherwise healthy, and a variety of anesthetic regimens can be used (see p. 976). If preoperative bloodwork suggests organ dysfunction (i.e., hepatic or renal), refer to Chapters 20 and 24, respectively, for specific anesthetic recommendations.

Surgical Anatomy

Refer to Chapter 33 for anatomy of the bone involved.

Positioning

Refer to Chapter 33 for exposure of the bone involved.

SURGICAL TECHNIQUE

Acute Osteomyelitis

Open infected wounds and debride necrotic tissue. If a fracture is present, stabilize bone fragments with an appropriate implant system (external skeletal fixators are usually preferred).

NOTE Stabilization of fractures is the key to successful treatment of osteomyelitis. Bone union will occur in the presence of infection if fragments are stable.

If previous surgery was performed, and if the fracture remains stable, leave the original implants in place. If the implants have loosened, choose another fixation system to provide rigid fixation. Establish drainage by treating the surgical site as an open wound. Irrigate the wound with 0.05% chlorhexidine, and then pack it with sterile gauze soaked with 0.05% chlorhexidine. Cover wounds with a sterile outer dressing that will absorb drainage products accumulated between bandage changes. Once the infection has been eliminated, suture the wound. Alternatively, close the wound over a continuous suction drain leaving the drain in place for 1 to 3 days depending on the amount and consistency of drainage.

Chronic Osteomyelitis

Determine the degree of fracture stability by palpation and radiographic assessment. If fractures and original implants are stable,

leave them in place. However, if implants are loose and fractures have not healed, remove the loose implants and rigidly stabilize the fracture. Identify and remove sequestered bone through radiographic imaging and surgery. At surgery, recognize sequestered bone as that having a yellowish discoloration with no soft tissue attachments. Do not try to stabilize sequestered bone fragments; instead, remove them and place an autogenous cancellous bone graft in areas devoid of bone. Establish drainage as described previously.

Antibiotic-impregnated polymethylmethacrylate beads may be considered for treating chronic infections, especially those associated with cortical allografts used for limb sparing. Bead strings are constructed using a bead mold in which the cement mixture is pressed onto stainless steel or nylon sutures. The strings are secondarily sterilized with ethylene oxide before implanting. The slow elution of the antibiotic can produce wound fluid concentrations up to 200 times those obtained with systemic antibiotics, exceeding the minimum inhibitory concentration for up to 80 days without toxic effects. The beads are usually removed after treatment.

SUTURE MATERIALS AND SPECIAL INSTRUMENTS

Aerobic and anaerobic culturettes should be available. Other instruments needed include those necessary for insertion of the selected implant, bone curettes, self-retaining retractors, and a selection of absorbable suture material. Nonabsorbable suture material should generally be avoided in infected tissue. Jackson-Pratt drains are useful for continuous suction drainage.

POSTOPERATIVE CARE AND ASSESSMENT

In patients with acute osteomyelitis, antibiotic therapy should be continued for at least 3 to 4 weeks. With chronic osteomyelitis, antibiotics should be administered for at least 4 to 6 weeks. If the wound is managed in an open fashion, the area should be irrigated with 0.05% dilute chlorhexidine twice daily and packed with a chlorhexidine-soaked sponge. Using umbilical tape secured to the skin on either side of the incision that can be tied over the gauze packing facilitates frequent changing of the packing materials. The limb should be bandaged until the wound is closed to decrease the likelihood of iatrogenic infection. Continuous closed suction drains are maintained for 1 to 4 days depending on the volume and consistency of the drainage. If a fracture is present, postoperative care is dictated by the fracture configuration and the stabilization procedure used. Generally, activity should be restricted to leash walks until the fracture has healed. Affected animals should be observed daily for signs of recurring fever, pain, swelling, and/or draining tracts and analgesic provided as appropriate (see Tables 13.2 and 34.3).

PROGNOSIS

If all bone sequestra are removed and fractures are adequately stabilized, the prognosis for resolving infection and returning the patient to normal activity is good. Removal of all implants following bone union is usually necessary to completely resolve infection.

37 Neurodiagnostic Overview for the Small Animal Surgeon

As the complexity of neurosurgical cases seen by surgeons and neurologists has increased, so has the complexity of diagnostic procedures and treatments. Many of the diagnostic procedures discussed in this chapter will be performed and/or interpreted primarily by neurologists and radiologists. Neurodiagnostic procedures include, but are not limited to, radiography, contrast radiography, ultrasonography, computed tomography (CT), magnetic resonance imaging (MRI), electrodiagnostic procedures (e.g., electromyography, nerve conduction studies), cerebrospinal fluid (CSF) examination, stereotactic brain biopsy, and nerve/muscle biopsy. Whereas a superficial understanding of more commonly performed electrodiagnostic procedures is more than sufficient for a surgeon's purposes, the same cannot be said about advanced imaging. In particular, it is imperative for the small animal surgeon who intends to maintain a foothold in neurosurgery to have at least a working knowledge of basic MRI physics and some experience in reading magnetic resonance images (see Chapter 14). Contrast radiography is almost completely outdated, with most private specialty and academic specialty hospitals preferentially using MRI for both brain and spinal cord disorders. The purpose of this chapter is to provide small animal surgeons with the fundamental principles of various neurodiagnostic modalities. The modalities of CT and MRI are not discussed in this chapter; they are covered in detail in Chapter 14.

RADIOGRAPHY AND CONTRAST RADIOGRAPHY

Indications

As noted previously, the roles of radiography and contrast radiography in modern veterinary neuroimaging have diminished tremendously coincident with ready availability of MRI. High-quality radiographs of the skull and vertebrae typically require sedation or general anesthesia and are generally low yield in comparison with CT and MRI. Despite this, certain disorders that cause bone lysis and/or production (e.g., skull tumors, diskospondylitis) will usually be apparent on survey radiographs (Fig. 37.1). In addition, survey radiographs are typically indicated in spinal trauma patients to evaluate for any obvious fractures or luxations (Fig. 37.2).

The most common contrast radiographic procedure performed in veterinary neurology is myelography, and although its use has almost disappeared in recent years, it is generally less costly and may be more readily available than CT or MRI in certain situations (e.g., emergencies). Myelography is a procedure in which spinal radiographs are obtained following injection of a radiopaque contrast agent into the subarachnoid space (Box 37.1). When used it may assist in the diagnosis of certain myelopathies where survey radiographs are normal or inconclusive despite neurologic evidence of myelopathy. Myelography can help estimate the location, extent, and severity of spinal lesions. The ability to easily and rapidly visualize the entire spinal cord is an advantage of myelography over CT and MRI. Myelography can be performed via a cisternal or lumbar tap. Cerebrospinal fluid should be collected before contrast injection because the contrast agent will change the composition of the CSF and may prevent accurate analysis for at least 3 to 5 days. Lumbar myelography often results in better image quality, even for lesions in the cervical region, and is safer than cisternal myelography. Techniques and dosages for myelography are provided in Box 37.1.

Complications and Contraindications

Despite the positive aspects of myelography, it is an invasive procedure associated with a low level of inherent risk (Box 37.2). Postmyelographic seizures have been reported to occur in up to 20% of dogs; this adverse event is more likely to occur in dogs larger than 20 kg and is more likely after cisternal versus lumbar contrast injections. The likelihood of postmyelographic seizure activity increases with increasing total volume of contrast agent injected (not the dose on a mL/kg basis). Male Doberman pinschers with caudal cervical spondylomyelopathy (i.e., "wobblers" syndrome) may also be particularly predisposed to postmyelographic seizure activity. Most patients that seizure will do so only once or twice in the 24 hours following the procedure, and seizures usually cease with intravenous (IV) diazepam injection (see Box 37.1). Administering a single IV dose of levetiracetam (20 mg/kg over 5 minutes) during anesthetic recovery appears to reduce the incidence of postmyelographic seizures. Maintaining slight elevation of the patient's head during and after the procedure (until the patient is awake) and ensuring hydration with IV fluids during and 24 hours after myelography will limit the occurrence and severity of postmyelographic seizures.

ABSTRACT

It is important for neurosurgeons to be familiar with a number of diagnostic modalities used in clinical neurology, including computed tomography (CT) and magnetic resonance imaging (MRI). Radiography is still used as a screening tool for several neurologic disorders; however, the use of contrast radiography has been declining with the increasing availability of MRI and CT. Nonetheless, it is still warranted in certain situations. Surgeons should be familiar with the basics of electrodiagnostic testing primarily so that they will have an understanding of what tests may be indicated for certain neurologic conditions. Familiarity with techniques for cerebrospinal fluid collection and the ability to interpret the results are also important.

FIG. 37.2 Lateral cervical radiograph of a dog with a comminuted cervical vertebral fracture.

BOX 37.1 Techniques and Dosages for Myelography

- Obtain cerebrospinal fluid for analysis before injecting contrast.
- Use a nonionic, iodinated, water-soluble contrast agent (e.g., iohexol, iopamidol).
- Administer a test injection (e.g., 0.5–1.0 mL, depending on patient size) initially to ensure that the contrast is in the subarachnoid space, before administering the remainder of the calculated contrast dose.
- For a regional study (e.g., cervical myelogram with cisternal contrast injection), inject 0.3 mL/kg body weight.
- For full studies (e.g., cervical myelogram with lumbar injection), inject 0.45 mL/kg body weight.
- Inject the contrast slowly—approximately 2–3 mL/min.
- Maintain slight elevation of the patient's head during and after the procedure (until the patient is awake), and ensure hydration with IV fluids during and for 24 hours after myelography.
- If seizures occur, administer IV diazepam injection (0.2–0.4 mg/kg).
- Administration of a single IV dose of levetiracetam (20 mg/kg over 5 min) during anesthetic recovery may reduce the incidence of postmyelographic seizures.
- Observe patient closely for the first 24 h following the procedure.

BOX 37.2 Contraindications and Potential Complications of Myelography

- Contraindicated in patients with:
  - Suspected inflammatory central nervous system disease
  - Elevated intracranial pressure
  - Historical or clinical indication of an underlying encephalopathy
- Potential complications
  - Seizures
  - Parenchymal damage from insertion of the needle
  - Transient neurologic worsening
  - Permanent neurologic worsening due to inadvertent contrast injection into the parenchyma or the central canal of the spinal cord

NOTE Whereas large-breed dogs with cervical lesions that have large volumes of contrast injected into the cerebellomedullary cistern may be particularly at risk for postmyelographic seizures, you should closely observe all dogs undergoing myelography (e.g., in an intensive care unit) for the first 24 hours following the procedure.

Other potential complications associated with myelography include parenchymal damage from insertion of the needle. Although this is rare, it may occur, especially in the cervical region. Worsened neurologic status post myelogram is usually caused by transient chemical myelitis secondary to contrast injection. The risk for this may be higher in patients with preexisting inflammatory disease or chronic spinal cord compression (e.g., chronic type II disk disease). The risk of transient neurologic worsening appears to be highest in dogs with caudal cervical spondylomyelopathy. These dogs typically regain premyelogram neurologic status within 72 hours. Inadvertent contrast injection into the parenchyma or the central canal of the spinal cord may cause worsened neurologic status. In most cases, patients recover from this iatrogenic trauma, but permanent deficits may remain in a small number of animals.

NOTE Myelography is contraindicated for patients with suspected inflammatory central nervous system (CNS) disease because it may cause worsened neurologic status. Myelography is also contraindicated in patients with possible elevated intracranial pressure (ICP). Because cervical hyperesthesia is occasionally associated with forebrain lesions, historical or clinical indication of an underlying encephalopathy should prompt consideration of an alternative imaging modality (e.g., CT, MRI).

Anatomy and Evaluation of Studies

Four basic myelographic patterns have been identified: normal, extradural, intradural/extramedullary, and intramedullary (Fig. 37.3). Normally, the contrast columns parallel each other and conform to the vertebral canal, except at the cauda equina region where the subarachnoid space tapers. The spinal cord ends at approximately the L6 vertebral region in most dogs and at the first sacral vertebral region in most cats, although much variation has been noted between breeds.

The spinal cord is normally wider at the cervical and lumbosacral intumescences. The ventral subarachnoid space is often

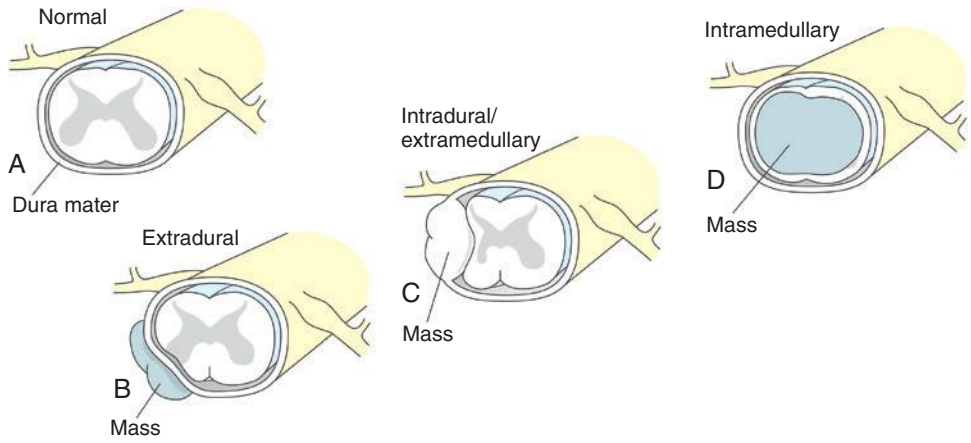

FIG. 37.3 Schematic illustrations demonstrating typical myelographic patterns for (A) normal, (B) extradural, (C) intradural/extramedullary, and (D) intramedullary lesions.

less prominent than the dorsal subarachnoid space in the thoracolumbar region in dogs. The dorsal subarachnoid space in the atlantoaxial region is often wider than the remainder of the spinal cord. The cervical spinal cord region in cats often appears wider on myelography compared to dogs. A normal myelographic pattern may be found in patients with degenerative myelopathy, fibrocartilaginous embolic myelopathy, and inflammatory myelopathies.

Extradural Pattern

Intervertebral disk extrusion/protrusion is the most common cause of an extradural myelographic pattern. Other causes of extradural patterns include vertebral fracture/luxation, congenital vertebral anomalies, hypertrophied soft tissue structures (e.g., interarcuate ligament, synovial membranes), extradural hemorrhage, vertebral neoplasia, and soft tissue neoplasia (e.g., feline lymphosarcoma). The nature of an extradural compression is best appreciated when viewed tangential to the direction of the cord deviation. For example, if a disk extrusion is compressing the cord from ventral to dorsal with no lateralizing component, the myelographic pattern as viewed from a ventrodorsal view (parallel with direction of compression) could be misinterpreted as intramedullary. With intervertebral disk extrusions, which are often ventrolateral (i.e., ventral but somewhat lateralized), it is usually helpful to obtain oblique views in addition to standard dorsal and ventral views to ascertain the correct side of disk extrusion for purposes of surgical planning. The accuracy of correctly identifying the side of disk extrusion is thought to be higher for oblique versus ventral views, but the accuracy is best when both views are obtained. Combining myelography with CT (CT/myelogram) is much more likely to provide accurate localization of disk extrusions than either CT or myelography alone.[1] Although CT alone is more likely to provide the correct side of a lateralized disk extrusion/protrusion than myelography alone, the author prefers to combine the two modalities if MRI is not an option. In dogs with more than one calcified disk extrusion/protrusion on CT imaging, it is common for only one site to be the active extrusion site; the others being old and inactive protrusions. In these situations, myelographic contrast best demonstrates the extent of spinal cord swelling (delineating which disk site is the active extrusion), whereas the CT provides better evidence (than myelography) of lateralization of the extrusion. MRI was superior to myelography for correctly identifying recurrent disk extrusions in dogs in one study.[2]

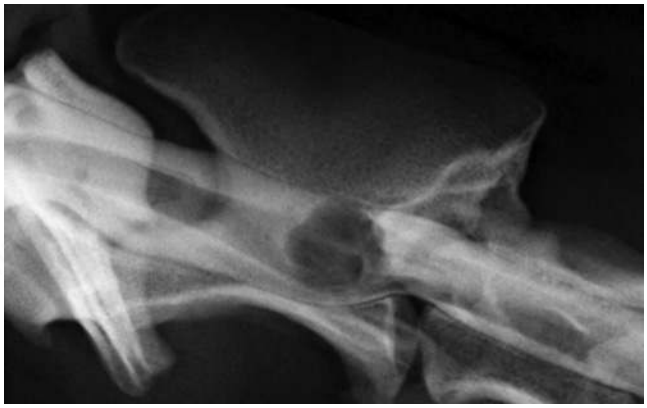

FIG. 37.4 Lateral myelographic appearance of a thoracolumbar lesion with a "golf tee sign," indicative of an intradural/extramedullary lesion.

Intradural/Extramedullary

An intradural/extramedullary pattern is produced when a lesion within the subarachnoid space (intradural) is not invading the parenchyma of the cord (extramedullary). As the contrast flows around the obstructive lesion, it may be outlined, appearing as a "filling defect." Sometimes, the filling defect is incompletely outlined and resembles a golf tee, hence the term *golf tee sign* (Fig. 37.4). Intradural/extramedullary patterns are most often associated with neoplasia, primarily meningiomas and nerve sheath tumors. Intradural hemorrhage may rarely lead to this myelographic pattern. Intradural/extramedullary lesions may produce enough spinal cord swelling that contrast is excluded from the region of the mass. In such cases, the myelographic pattern may appear to be intramedullary; a CT is often performed through the abnormal region because contrast is better visualized on CT images.

Intramedullary

An intramedullary pattern is typically associated with spinal cord edema, expansile parenchymal masses, or intraparenchymal

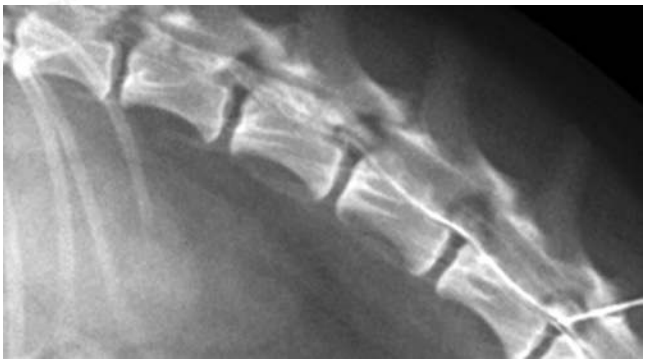

FIG. 37.5 Lateral myelographic view of a dog with myelomalacia. Note the mixing of the contrast agent with the spinal cord parenchyma.

hemorrhage. Differential diagnoses include fibrocartilaginous emboli, neoplasia (e.g., astrocytoma, lymphosarcoma), inflammatory disorders (e.g., granulomatous meningoencephalitis in dogs, feline infectious peritonitis [FIP] in cats), and trauma (e.g., hemorrhage, edema). In addition to apparent spinal cord swelling on myelographic images, contrast leakage into the spinal cord parenchyma may be appreciated in cases of spinal cord myelomalacia (Fig. 37.5).

Epidurography and diskography are infrequently performed contrast radiographic procedures used to evaluate the cauda equina region. *Epidurography* involves injection of contrast agent into the epidural space at the L7-S1 space, the sacrocaudal junction, or between coccygeal (caudal) vertebrae. *Diskography* entails injection of contrast agent directly into the L7-S1 disk, something that can be done only if the disk is degenerate. A combination diskogram/epidurogram can also be performed.

To perform a combination diskogram/epidurogram, inject the disk first, take radiographs, then withdraw the needle from the disk so that the needle tip is in the epidural space. Inject contrast again and obtain additional radiographs.

ELECTRODIAGNOSTICS

Electrodiagnostic examinations take advantage of the body's electrical properties to help characterize neurologic disorders. These tests require specialized instrumentation and require that individuals be trained in performing and interpreting the tests. Electrodiagnostic testing in dogs and cats has declined substantially, coincident with advances in neuroimaging. Despite the plethora of electrodiagnostic procedures available, only a handful of these tests are done on a regular basis. In clinical practice, the most frequently performed electrodiagnostic procedures are electromyography (EMG) and motor nerve conduction velocity (MNCV). Muscle/nerve biopsy is often performed after these procedures (see Chapter 44). The most common site for muscle/nerve biopsy is the region of the common peroneal nerve. Two main categories of electrical activity are measured in clinical neurology: spontaneous and evoked. Spontaneous potentials are electrical signals that are produced by the body in the absence of an externally applied stimulus. Evoked potentials are electrical impulses caused by an externally applied stimulus.

Electromyography

Electromyography is the recording of spontaneous electrical activity from muscle. *Perform this test with the patient under general anesthesia. Use a concentric needle electrode. Insert the needle electrode into muscle tissue and record muscle activity. Reposition the needle several times to sample different areas of the muscle belly and evaluate multiple muscles. Evaluate both the sound and the appearance of spontaneous muscle activity during the study (Table 37.1).*

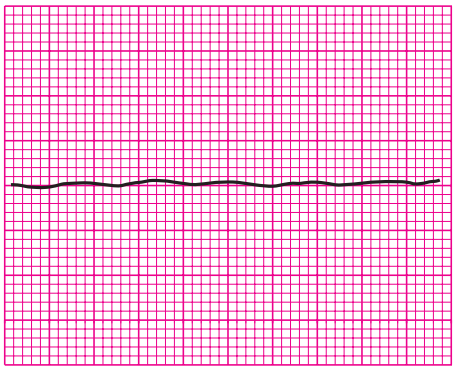

FIG. 37.6 Normal silent electromyographic tracing from a dog.

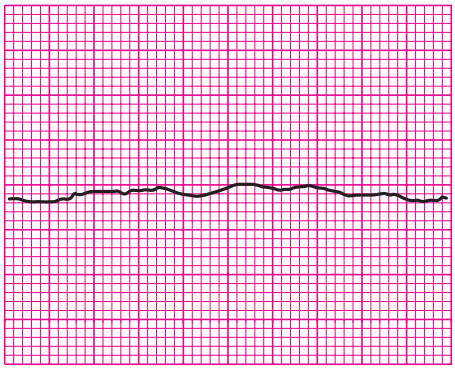

FIG. 37.7 End plate potentials recorded from a normal dog.

Abnormal muscle activity from EMG evaluation is sensitive but not specific; muscle fibers often become hyperexcitable with both denervation (due to neuropathies) and more direct damage (myopathies). Therefore abnormal EMG activity confirms the presence of a neuropathic or myopathic process but is not specific for either. Electromyographic abnormalities may not be detectable for 5 to 7 days following denervation. Not all myopathies or neuropathies are characterized by abnormal EMG activity. Muscle tissue is generally silent on EMG evaluation (Fig. 37.6) of the anesthetized patient. Small deviations from baseline (monophasic potentials) are occasionally recorded from muscles, especially near motor points (sites where major nerve trunks connect with muscle bellies). This normal activity is called *end plate noise* or *end plate potentials* and reflects small depolarizations (miniature end plate potentials) at neuromuscular junctions (Fig. 37.7). End plate noise sounds similar to small waves breaking at the seashore or the sound heard when one listens to a sea shell. Immediately after insertion of the needle electrode into a muscle belly, a short burst of electrical activity (i.e., insertional activity) typically occurs. This is due to mechanical irritation and damage to muscle fibers by the needle and is normal unless it lasts longer than 1 to 2 seconds after the needle stops moving. Replacement of muscle tissue by fat or connective tissue in chronic denervation or myopathies may lead to the absence of insertional activity.

TABLE 37.1 Abnormal Electromyographic Activity

Terminology	Sound	Interpretation	Clinical Implications
End plate noise or end plate potentials	Small deviations from baseline (monophasic potentials). Sound like waves on the beach.	Normal; reflects small depolarizations (miniature end plate potentials) at neuromuscular junctions. More prominent at motor points—where a nerve enters a muscle group.	If absent, may be due to specific location of needle (not near a motor point). If absent near motor points, may reflect replacement of muscle tissue by fat or connective tissue because of chronic neuropathy or myopathy.
Insertional activity	Transient deviations from baseline. Positive or negative cluster of high-frequency spikes with a crisp static sound—much like the sound of a hand moving over a fully inflated balloon. Also referred to as *injury potentials.*	Normal unless it lasts longer than 1 to 2 sec after the needle stops moving. This activity is due to muscle fibers mechanically stimulated or damaged by needle insertion.	Absence of this activity may occur with replacement of muscle tissue by fat or connective tissue in chronic denervation or myopathies.
Fibrillation potentials	When single, popping noises; when occurring as a train or continuous run, like eggs or bacon frying or a heavy rain falling on a tin roof	Abnormal—occurs with denervation or myopathies	Severe or chronic neuropathy or myopathy
Positive sharp waves	When occur in a train or burst, may sound like a racecar	Abnormal—occurs with denervation or myopathies	Neuropathy or myopathy
Complex repetitive discharges	Revving motorcycle engines or airplanes flying	Abnormal—occurs with denervation or myopathies	May be from bared muscle spindles; often associated with chronicity
Myotonic discharges	"Dive-bomber" sound. Unlike complex repetitive discharges, these have both waxing and waning components.	Typically recorded following needle electrode insertion or repositioning	Myotonia (congenital or due to hyperadrenocorticism)

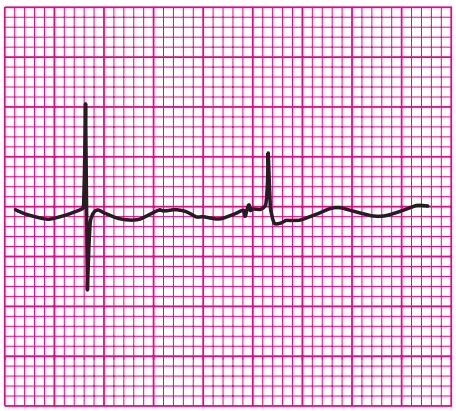

FIG. 37.8 Fibrillation potentials.

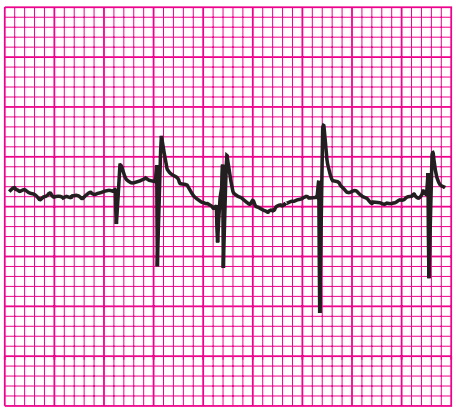

FIG. 37.9 Positive sharp waves.

In addition to prolonged insertional activity, abnormal EMG activity includes fibrillation potentials, positive sharp waves, and complex repetitive discharges. In general, all of these abnormal potentials indicate neuropathy or myopathy but are not specific for either. Fibrillation potentials are biphasic or triphasic spikes of short duration that are thought to arise from individual muscle fibers (Fig. 37.8). They sound like popping noises. When occurring as a train or a continuous run, the sound is like that of eggs or bacon frying, or a heavy rain falling on a tin roof. Fibrillation potentials are believed to represent severe or chronic disease, compared with positive sharp waves. Positive sharp waves often occur concurrently with fibrillation potentials. These potentials are of longer duration than fibrillation potentials and appear to be monophasic (Fig. 37.9). Positive sharp waves are believed to originate from individual muscle fibers, but a conduction block in the sarcolemma leads to the more prolonged potential. When positive sharp waves occur in a train or burst, it sounds like a race car driving past. Complex repetitive discharges or bizarre high-frequency potentials are synonymous catch-all terms applied to polyphasic potentials that do not appear to be fibrillation potentials or positive sharp waves. These potentials are thought to arise from bared muscle spindles and are often associated with chronicity. They tend to have constant amplitude and frequency (i.e., do not wax and wane). The sounds of these potentials are varied and have been described as revving motorcycle engines and airplanes flying. Myotonic discharges are often described as a distinct entity, rather than a subcategory of complex repetitive discharges. These are high-frequency, biphasic or

triphasic repetitive discharges that wax and wane, producing a "dive-bomber" sound. They are typically recorded following needle electrode insertion or repositioning. Although not specific for any disorder, these discharges are most often associated with myotonia (congenital or due to hyperadrenocorticism).

Electroencephalography

Electroencephalography (EEG) refers to the recording of spontaneous electrical activity of the cerebral cortex and the interpretation of these recordings. Historically, EEG had many practical applications, including its use in localizing seizure foci. In modern veterinary neurology, the clinical utility of EEG examination is low. The likelihood of EEG examination contributing substantially to the management of a patient with an established generalized seizure disorder is negligible. EEG is fairly inaccurate for localizing focal brain abnormalities, and it provides no structural information. EEG may be helpful in cases of focal seizure disorders in which the diagnosis of the condition as a seizure disorder is sometimes equivocal. EEG examination may also be useful as a determinant of brain death in comatose patients who have been resuscitated following cardiac arrest. A high degree of subjectivity is involved in the interpretation of abnormal EEG recordings. In general, frequencies and amplitudes that appear inadequate or excessive for the physiologic conditions under which they are measured (e.g., high-voltage, slow-frequency activity in an awake patient) are indicative of brain dysfunction. Spike and spike-wave activity (Fig. 37.10) are indications of a seizure disorder.

Brainstem Auditory Evoked Response

Brainstem auditory evoked response (BAER) testing utilizes the auditory pathway for evaluation of hearing and brainstem disorders. The patient is administered auditory stimuli in the form of clicks delivered via specialized ear plugs. The resultant evoked response is measured via subcutaneous scalp electrodes arranged in specific patterns. The normal BAER consists of four or five waves that are time-locked to the sound stimulus (Fig. 37.11). These waves appear within 10 ms of the sound delivery. The BAER is not appreciably affected by sedation or anesthesia, so it can be performed on awake, sedated, or anesthetized patients. The waves of the BAER correspond to sequentially stimulated neuronal groups and white matter tracts associated with the auditory pathway. These waves represent a caudal-to-rostral chain of propagated depolarization, starting from the cochlear portion of cranial nerve VIII and ending at the caudal colliculus (midbrain) and medial geniculate (thalamus) region. The appearance and latency (time between sound stimulus and appearance of the wave) of each wave following the first wave are dependent on the integrity of neural tissue caudal to the site of generation of the specific wave, as well as on the tissue constituting the generator site for that specific wave. With congenital hearing disorders, the BAER is typically a flat line because no wave I and therefore no subsequent waves are present. Interwave intervals and left-right comparisons can be used to discern whether a brainstem lesion is present in patients with intact hearing. With brain death (e.g., cardiac arrest), the BAER may be a flat line or may have one or two initial waves, with the remaining waves being absent. Because the inner ears are very susceptible to hypoxemia, an EEG should be performed in an arrest patient with a flat BAER study to discern hypoxia-related deafness versus brain death.

Motor Nerve Conduction Velocity

MNCV studies are performed primarily in animals suspected of having neuropathies. For MNCV measurement, an electrical stimulus is applied to a nerve with subcutaneous electrodes, and the resultant depolarization of a muscle supplied by that nerve is recorded with a recording electrode. The depolarizing event is a large biphasic or triphasic muscle potential formed by action potentials of many muscle fibers from many motor units. It is typically referred to as a *compound muscle action potential (CMAP)* or an *M wave*. The latency or the time from the stimulus to onset of the M wave is measured by the computer. A minimum of two sites of a nerve must be stimulated to calculate an MNCV. The distance between the two stimulation sites (in meters) is divided by the difference in latency from stimulus artifact to M wave appearance for the two sites (in seconds) to arrive at MNCV in m/sec. The M wave is the result of orthodromic (proximal to distal) propagation of nerve depolarization.

FIG. 37.10 Spike and spike-wave activity from an electroencephalographic recording of a patient with idiopathic epilepsy. (Courtesy Dr. Dan Fletcher.)

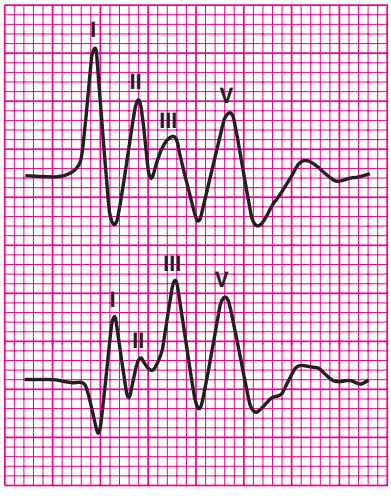

FIG. 37.11 Normal brainstem auditory evoked response recording from a cat.

When a nerve is artificially stimulated, as in MNCV testing, it also depolarizes distally to proximally. Measurement of F waves takes advantage of this phenomenon. The depolarization that travels proximally in a stimulated nerve will cause the lower motor neurons of that nerve to depolarize. This depolarization will cause a second orthodromic (proximal-to-distal) impulse propagation and a smaller and more delayed compound muscle action potential called the *F wave.* This test has limited utility in veterinary medicine, but it can be used to assess the integrity of ventral roots in disorders like polyradiculoneuritis or brachial plexus injuries.

General anesthesia is required for MNCV measurement. If the patient has clinical evidence of a generalized disorder (e.g., suspect polyneuropathy), the sciatic nerve and its branches (i.e., peroneal or tibial nerves) may be preferable test sites. After a nerve is severed, axons distal to the severed area will continue to conduct normally for up to 4 days. The nerve is stimulated at two or three sites, and the MNCV is calculated after the distance from stimulating to recording electrodes is manually measured (Fig. 37.12). This measurement is performed using a tape measure and is the most likely source of error in this test (Box 37.3). Characteristics of MNCV are provided in Box 37.3. Small-amplitude M waves or polyphasic M waves are often indicative of neuropathy but may result from myopathies.

Sensory Nerve Conduction Velocity

Sensory nerve conduction velocity (SNCV) is less commonly performed in dogs and cats than MNCV measurement. This test is typically performed by stimulating a distal cutaneous nerve branch and measuring compound action potentials over proximal sites on the parent nerve. The technique is similar to that used for MNCV, but the depolarization events of interest are directed proximally, and compound action potentials are from axonal depolarization and therefore are of much smaller magnitude than the CMAPs or M waves recorded in MNCV studies. SNCV recording is primarily used to evaluate patients with suspected neuropathies, especially if MNCV evaluation is normal or equivocal. It is generally thought that SNCV is more sensitive to early neuropathic processes compared with MNCV.

BOX 37.3 Considerations for Motor Nerve Conduction Velocity (MNCV) Measurement in Dogs and Cats

- Using a tape measure for nerve length estimate is a potential source of error.
- Normal MNCV
  - In older patients: at least 50 m/s
  - In young to middle-aged patients: usually >60 m/s
- Decreased body temperature causes MNCV to decrease by 1.8 m/s for each degree Celsius below normal.
- Proximal nerve segments normally conduct faster than distal nerve segments.
- Demyelination is more likely to affect MNCV than is axonal loss.
- Small-amplitude or polyphasic M waves often indicate neuropathy (may result from myopathies also).

Repetitive Nerve Stimulation

The **repetitive nerve stimulation** (RNS) test measures successive CMAPs (M waves) induced by repetitive stimulation of the nerve that supplies the muscle from which the potentials are recorded. With stimulation rates of five or fewer per second, the sequential M waves should be of equal amplitude and area as the first. A decremental response of 10% or greater indicates a problem with neuromuscular transmission. Although not specific for the disease, a decrementing RNS is usually indicative of myasthenia gravis (MG) (Fig. 37.13). General anesthesia is required for RNS in dogs and cats. Stimulating the peroneal nerve at the knee or hock level and recording from a digital muscle are recommended.

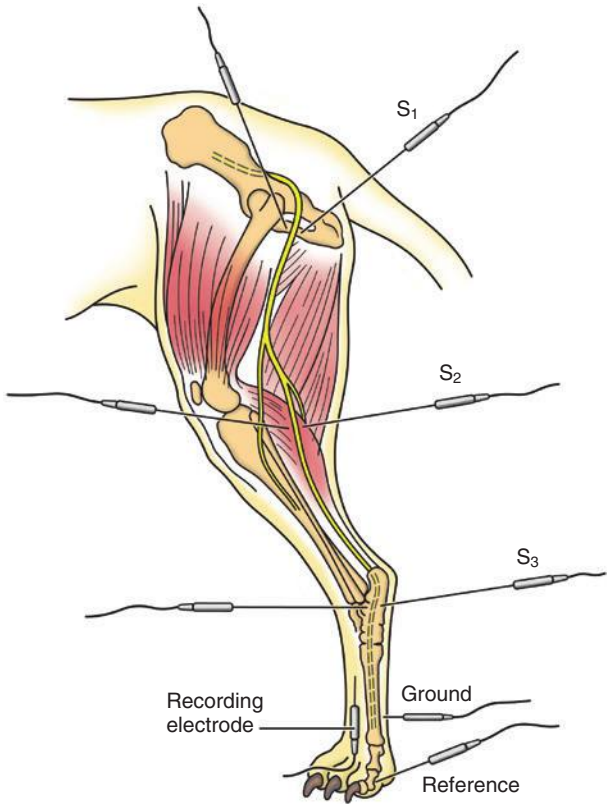

FIG. 37.12 Schematic illustration of the typical setup for motor nerve conduction velocity measurement of the sciatic and peroneal nerves.

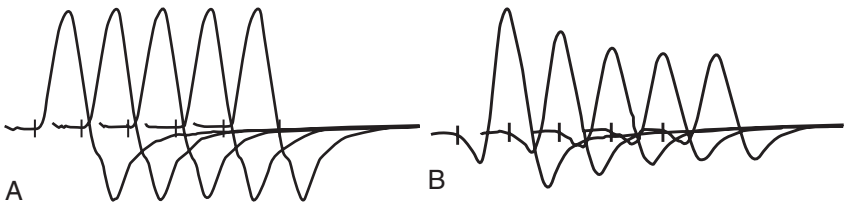

FIG. 37.13 (A) Normal repetitive nerve stimulation (RNS) result compared with (B) a decrementing RNS recording. The latter recording is from a myasthenic dog.

The setup is the same as for MNCV, but only one stimulation site is necessary for RNS. In cases of focal MG, the limb RNS is sometimes normal. In suspect cases of focal MG with normal limb RNS, a decremental response in facial musculature (e.g., orbicularis oculi muscle) following facial nerve stimulation is often seen.

CEREBROSPINAL FLUID ANALYSIS

CSF should be collected from patients before contrast radiographic procedures and often after a CT or MRI examination. The cell count and protein level of the CSF can be thought of as the CNS analog of the complete blood count (CBC) and serum protein level for the systemic circulation, respectively. Abnormal CBC and serum protein results often assist in the diagnosis of systemic illness when viewed in the context of other laboratory abnormalities, as well as historic complaints and clinical findings. These abnormalities are typically not indicative of any specific disease when viewed as isolated test results. Similarly, results of CSF analysis often contribute to a diagnosis, but rarely by themselves provide a specific diagnosis. CSF analysis is very sensitive in that it is often abnormal in patients with neurologic disease; however, it is highly nonspecific in most cases. Collection and evaluation of CSF are indicated for encephalopathies and myelopathies for which imaging suggests an inflammatory process. For other disorders of the brain and spine (e.g., neoplasia), CSF evaluation may be helpful; however, the potential benefits of CSF collection and evaluation in such cases should be weighed against the potential risk to the patient and additional expense. In most cases of brain neoplasia, CSF collection does not represent a substantial risk, but tentorial herniation is possible, especially if the ICP is very high. Furthermore, CSF collection is not likely to add substantially to the diagnosis. If surgical removal of a well-delineated brain or spinal mass is planned, CSF evaluation is not likely to alter that plan.

To perform a CSF tap, collect 1 to 1.5 mL (approximately 10 drops) of CSF in a sterile glass tube, preferably without ethylenediaminetetraacetic acid (EDTA) (e.g., red-top tube). Collect both a red-top sample (for protein and cell concentrations and culture) and a purple-top (EDTA) sample (for cellular morphology) for analysis. Generally, you can remove 1 mL per 5 kg body weight of CSF safely at one time for analysis. EDTA may falsely elevate protein concentrations and falsely lower cell concentrations in small samples. Because EDTA is bactericidal, it may interfere with CSF culture results in cases of CNS bacterial infection; however, EDTA may help preserve cellular morphology.

CSF is most commonly obtained from the cerebellomedullary cistern (cisternal tap). CSF collected from this site may be more representative of lesions involving the brain than CSF collected from a lumbar puncture. The widely held belief that lumbar punctures are safer than cisternal punctures in cases of increased ICP is not substantiated clinically. However, if cerebellar herniation is obvious on sagittal MRI with compromise of the cerebellomedullary cistern, a lumbar puncture is preferred. Anatomic landmarks useful in performing cisternal CSF taps include the external occipital protuberance, the cranial aspect of the dorsal spine of the axis (C2 cervical vertebra), and the transverse processes ("wings") of the atlas (C1 cervical vertebra).

Cisternal Puncture

Use a noncollapsing endotracheal tube to avoid occluding airflow during the procedure (avoid red rubber endotracheal tubes because these tubes are more prone to complete kinking with neck flexion when compared with polyvinyl chloride [PVC] endotracheal tubes). Shave and aseptically prepare the skin in the region of the tap. Place the patient in lateral recumbency and have an assistant flex the neck. Keep the animal's nose parallel with the table. Have the assistant "tuck in" the animal's chin, and push the external occipital protuberance toward the individual performing the tap (Fig. 37.14). Place a form of support under the neck (e.g., rolled-up paper towel) to help keep the spine of the axis and the external occipital protuberance inline.

While wearing sterile gloves, insert a 22-gauge spinal needle with a stylet (20-gauge in larger patients) on the midline, directing it toward the occipitoatlantal space. Estimate the proper location for needle insertion by locating the cranial aspect of the C2 spine with an index finger, then press firmly with the fingertip as the finger is simultaneously advanced cranially. In most patients, you

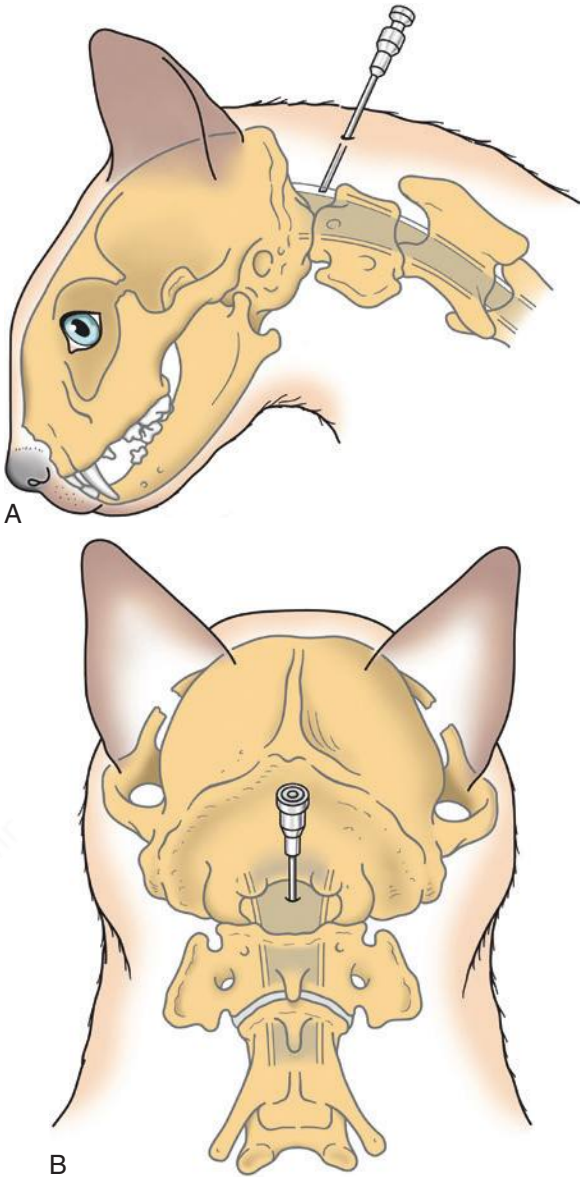

FIG. 37.14 Anatomic landmarks for cerebellomedullary cisternal cerebrospinal fluid collection in the cat. (A) Lateral view. (B) Dorsoventral view.

will palpate a ridge or divot approximately one-third of the distance between the cranial aspect of the C2 spine and the external occipital protuberance. This ridge is the cranial aspect of the arch of C1.

Insert the needle just cranial to the ridge to allow entry into the occipitoatlantal space. Alternatively, draw an imaginary line across the cranial limits of the wings of C1 and a perpendicular line from the external occipital protuberance caudally. Insert the needle at the intersection of these lines. Puncture the skin first, then use the index finger and thumb of one hand (left hand for a right-handed person) to stabilize the needle against the skin surface as the other hand slowly advances the spinal needle. After every few millimeters of advancement, remove the stylet to observe for CSF flow. Typically, you will feel the needle pass through fibrous tissue planes, producing a "popping" sensation; however, this is not consistent. *If the needle abuts bone, redirect the tip slightly cranial or caudal into the dorsal subarachnoid space.* If the needle tip is pushed through the cord and lacerates the basilar artery, severe complications can ensue.

Lumbar Puncture

Lumbar puncture for CSF collection (lumbar tap) is usually performed at the L4-L5 space in large dogs or at the L5-L6 space in smaller dogs and cats (Fig. 37.15). Lumbar CSF may be more representative of lesions involving the thoracolumbar spinal cord than CSF from a cisternal puncture. *Place the patient in lateral recumbency and shave and aseptically prepare the skin at the puncture site for CSF collection. Advance the patient's pelvic limbs cranially to open up the interarcuate space. Face the ventral aspect of the patient, and bend over the patient to insert the spinal needle. Insert the spinal needle just lateral to midline, adjacent to the caudodorsal limit of a spinous process (L6 for L5-L6 puncture; L5 for L4-L5 puncture). Insert the needle at a 30- to 60-degree angle from an imaginary line drawn perpendicular to the long axis of the spine.* After the interarcuate space is entered, the needle will pass through the dorsal dura mater. Often at this point, a twitch of the pelvic limbs and/or tail will be noted. *Advance the needle to the floor of the vertebral canal, and withdraw the stylet. Allow CSF to drip into a collection tube.*

Although the spinal needle penetrates the spinal cord during a lumbar CSF tap, this does not appear to cause any clinical problems.

A variety of tests can be performed on CSF; the most clinically useful of these is cell count with differential and protein concentration (Box 37.4). For some diseases (e.g., canine distemper virus, FIP [coronavirus] CNS infection in cats), amplification of genetic material via polymerase chain reaction may be indicated. Ideally, cell counts should be performed within 30 minutes of CSF collection; however, recent evidence indicates that reliable cell counts may be obtained up to 48 hours later if the CSF is preserved through the addition of autologous serum.

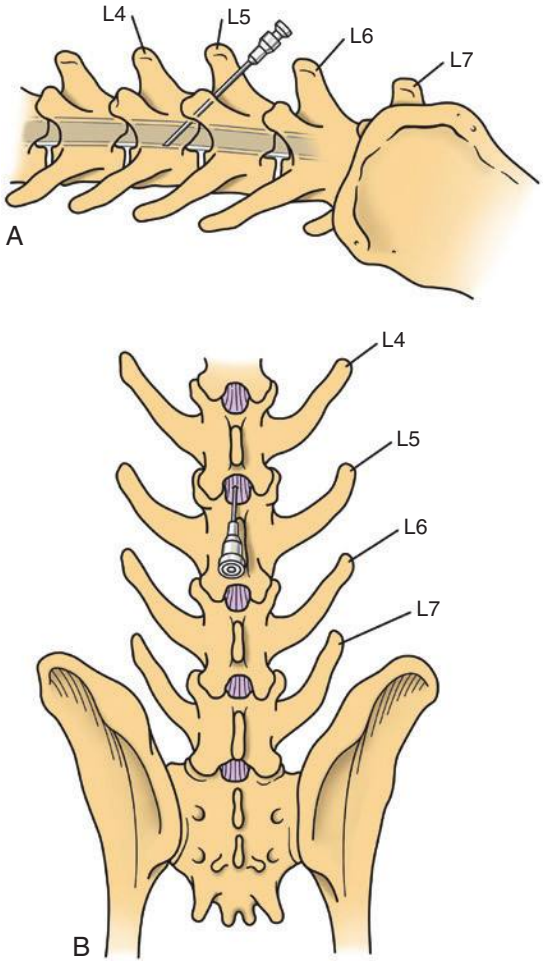

FIG. 37.15 Anatomic landmarks for obtaining cerebrospinal fluid via lumbar puncture in the dog. (A) Lateral view. (B) Dorsoventral view.

NOTE Prior treatment may alter the expected results of CSF analysis, especially in patients with inflammatory disease treated with corticosteroids.

Normal CSF is clear and colorless and has the consistency of water. Prior hemorrhage (occurring a minimum of 10 hours before CSF collection) in the CSF may result in a yellow tinge, referred to as *xanthochromia*. This discoloration can persist for 2 to 4 weeks following hemorrhage into the subarachnoid space

BOX 37.4 Interpretation Guidelines for Canine and Feline Cerebrospinal Fluid

Normal Nucleated Cell Count
<5 cells/μL

Normal Protein Concentration
<27 mg/dL cisternal tap
<45 mg/dL lumbar tap

Effect of RBC Contamination on Nucleated Cell Count
Dogs: 500 RBCs/μL = 1 WBC/μL
Cats: 100 RBCs/μL = 1 WBC/μL

Effect of RBC Contamination on Protein Concentration
1200 RBCs/μL = 1 mg/dL protein

Effects of RBCs and WBCs on CSF Turbidity
Turbidity from WBCs: >200 WBCs/μL
Turbidity from RBCs: >400 RBCs/μL

CSF, Cerebrospinal fluid; *RBC,* red blood cell; *WBC,* white blood cell.

but is usually resolved by 4 to 8 days. Other potential causes for xanthochromia include severe icterus and markedly elevated CSF protein levels.

Gross blood contamination may be iatrogenic or may result from ongoing hemorrhage in the subarachnoid space. Iatrogenic hemorrhage is more common with lumbar taps than with cisternal taps. Although iatrogenic hemorrhage interferes with interpretation of CSF results, the extent to which it does so is controversial. It has been suggested that each 500 to 700 red blood cells (RBCs)/mL in a hemorrhagic CSF tap may account for one white blood cell (WBC)/mL in dogs, and each 100 RBCs/mL may account for one WBC/mL in cats (see Box 37.4). However, it has also been demonstrated that RBC counts in CSF as high as 15,000/mL can occur with minimal elevation of the WBC count. The effect of hemorrhage on CSF protein levels is typically low; approximately 1200 RBCs/mL is needed to increase the protein concentration by 1 mg/dL.

Increased turbidity of CSF is usually due to an elevated number of cells (more than 200 WBCs/mL, more than 400 RBCs/mL) and is occasionally due to increased protein levels (see Box 37.4). Elevated protein levels in CSF will cause the fluid to be more viscous. CSF that clots is rare and is caused by a markedly increased protein concentration.

Although the actual number may vary with the laboratory used, fewer than five nucleated cells per mL of CSF are usually present (see Box 37.4). In normal dogs and cats, lumbar CSF typically has fewer WBCs/mL than cisternal CSF. The distribution should predominantly consist of mononuclear cells with only occasional neutrophils.

Although each laboratory will establish normal ranges, normal protein concentration for cisternal CSF is less than 27 mg/dL in dogs and cats (see Box 37.4). Normal protein levels will be higher when the CSF is collected from a lumbar puncture (approximately twice that of cisternal CSF, or <45 mg/dL).

Generally, the greater the meningeal or ependymal involvement, the greater the number of WBCs expected in the CSF. Deep-seated parenchymal lesions may be associated with mildly increased or normal cell counts, often with elevated protein levels. Increased nucleated cell counts in the CSF are referred to as *pleocytosis*. A normal cell count with an elevated protein level is often referred to as *albuminocytologic dissociation*.

A neutrophilic pleocytosis is often associated with bacterial infection and corticosteroid-responsive (aseptic) meningitis. Other diseases in which neutrophils may predominate in CSF include some viral encephalitides (e.g., acute canine distemper infection, FIP meningoencephalitis in cats), fungal infections, meningiomas, and fibrocartilaginous embolic myelopathy. Neutrophils associated with infectious disease (e.g., bacterial meningoencephalitis) are more likely to degenerate than those that occur in noninfectious (e.g., corticosteroid-responsive meningitis) disorders.

Mononuclear cell pleocytosis refers to a predominance of lymphocytes or macrophages in the CSF. This is the most common pleocytosis encountered and is usually associated with granulomatous meningoencephalitis in dogs (see p. 1453). The necrotizing encephalitides (i.e., pug/Maltese encephalitis, Yorkshire terrier encephalitis) are usually characterized by primarily lymphocytic pleocytosis. Lymphosarcoma involving the CNS may also be associated with a lymphocytic pleocytosis. A predominantly mononuclear pleocytosis can be caused by fungal, viral (e.g., canine distemper virus), protozoal, rickettsial, and chronic bacterial infections.

Eosinophilic pleocytosis is rare. It has been associated with aberrant parasite migration in the CNS, rabies virus, and cryptococcal, protozoal, and protothecal infections. A rare idiopathic condition called *eosinophilic meningoencephalitis* is characterized by a substantial proportion of eosinophils in the CSF.

38 The Neurologic Examination and Relevant Neuroanatomy

Performing and interpreting a neurologic examination in dogs and cats requires a working knowledge of functional and dysfunctional neuroanatomy; an in-depth understanding of neuroanatomy is not necessary for proficiency in localizing their neurologic lesions. A neurologic examination is performed in a systematic fashion and can, in most cases, be done within 10 to 15 minutes. The two important questions to be answered by the neurologic examination are (1) Does the patient have neurologic disease? and (2) If so, where is the lesion? A number of principles should be followed when localizing lesions in small animals. Although fairly specific neurologic localization should be attempted, all lesions will be in one of three general locations: brain, spinal cord, or peripheral nervous system. The anatomic subdivisions within each of these locations are provided in Box 38.1. The order chosen for the various tests performed during the neurologic examination is not important, but the order of the examination should be consistent so that nothing is forgotten. Manipulations that may result in a painful patient response should be done at the end of the neurologic examination. The neurologic examination may need to be modified in certain situations (e.g., hemiwalking would not be advised in a suspected thoracolumbar fracture/luxation patient). Performing abbreviated neurologic examinations or "quick looks" should be avoided; the responsibility for incorrect localization of a lesion will fall upon the examiner, and having performed an incomplete neurologic examination will not be a viable excuse for an error. Ambulatory patients should be allowed to navigate the examination room before the "hands on" part of the neurologic examination. This allows the surgeon to evaluate for circling behavior, visual deficits (e.g., bumping into objects), and gait abnormalities. Palpation of the entire animal is recommended to evaluate for areas of muscle atrophy, particularly in thick-haired patients in which atrophy is less visible. The components of a standard neurologic examination include evaluation of mental status, cranial nerves, attitude/posture, gait, postural reactions (proprioception), spinal reflexes, and nociception (normal and abnormal pain responses).

MENTAL STATUS

A patient's mental status reflects the integrity of the cerebrum, as well as parts of the brainstem (ascending reticular activating system). Anatomically, the diencephalon is the rostralmost aspect of the brainstem. Because diencephalic lesions cause clinical signs that are often indistinguishable from cerebral lesions, the term *forebrain* (cerebrum/diencephalon) is often used clinically to distinguish this part of the brain from the remainder of the brainstem. The major subdivisions of the brain are displayed graphically in Fig. 38.1. In dogs and cats with altered mentation, it is sometimes necessary to describe both the quality and the content of mental status. The quality of mentation refers to the level of alertness; this ranges from a normal level of alertness to coma. Between these two extremes are obtundation and stupor (Table 38.1). *Obtunded* animals tend to appear depressed, listless, and disinterested in spontaneous activity. Although these patients often appear drowsy, they are easily aroused with a minor stimulus (vocal cues, other noises). Unlike other forms of depression (e.g., those due to metabolic disease), obtunded patients are often described as appearing "out of it." *Stupor* describes a dog or cat that is not conscious but can be aroused with a strong stimulus (e.g., toe pinch). *Coma* refers to a state of unconsciousness that persists even after the application of a strong stimulus. Although not absolute, stupor and coma are often indicative of brainstem lesions (i.e., midbrain through medulla), whereas obtunded mental status is often associated with forebrain disease (i.e., cerebrum/diencephalon). Some patients, particularly those with forebrain dysfunction, will display an alert (but abnormal) quality or level of mental status with abnormal content of consciousness (e.g., dementia associated with cognitive dysfunction). Behavioral abnormalities are separate from mental status changes, although a fine line may be present between these two assessments. Subtle behavioral changes may not be apparent to the examiner; in such situations, the owner's assessment of their pet's behavioral status is crucial.

CRANIAL NERVES

The twelve cranial nerves and their associated functions are summarized in Table 38.2. The locations of these nerves in relation to the brain subdivisions from which they originate are shown in Fig. 38.2. Cranial nerve examination is straightforward and easily performed. It is customary and appropriate for the clinician to think of each cranial nerve in terms of its region or origin in the brain because dysfunction of a cranial nerve may represent damage to the neurons in a nucleus comprising that nerve (brain lesion) or to the nerve itself. It should be kept in mind that these nerves must travel a variable distance to their respective foramina, so there are clinical situations in which a specific cranial nerve is compromised at some distance from its associated brain subdivision (e.g., cavernous sinus syndrome). The cranial nerves and their respective brain origins are as follows: cranial nerves (CNs) I and II—forebrain (cerebrum/diencephalon); CNs III and IV—midbrain (mesencephalon); CN V (motor only)—pons (ventral metencephalon); and CNs VI through XII—medulla (myelencephalon). The sensory nucleus and the tract of CN V is very extensive and is found from the midbrain rostrally to the

ABSTRACT

All small animal surgeons should be proficient at performing and interpreting the results of a neurologic examination. Although neuroanatomy may appear to be a daunting obstacle to overcome for many clinicians, the working knowledge of functional neuroanatomy required for clinical proficiency in consistently accurate neurolocalization is not overwhelming. This chapter provides a concise and logical review of the necessary components of the neurologic examination for small animal patients, along with the relevant neuroanatomy associated with these components.

first few cervical spinal cord segments caudally. CNs IX, X, and XI act in combination to perform the same basic functions (laryngeal, pharyngeal, and esophageal innervation), so they can be thought of collectively as one cranial nerve.

CN I or the *olfactory nerve* is routinely ignored because it is difficult to assess the modality of smell. CN II or the *optic nerve* conveys the sensory modality of vision. Visual ability can be assessed in a number of ways. Probably the most common test performed for evaluation of vision is the menace response. This is a learned response (should be present by 3 months of age in dogs and cats) and therefore is not a reflex. When a menacing gesture is made toward the patient with the examiner's hand, the appropriate response is for the patient to blink (Fig. 38.3 and Video 38.1). The afferent part of this response is conducted by CN II, and the efferent part (the blink) is accomplished via the facial nerve (CN VII). Visual following is somewhat objective, especially with cats. In this test, objects (such as cotton balls or toys) are thrown or dropped in front of the patient; the normal expectation, if vision is intact, is for the patient's eyes and head to follow the objects. CN III or the *oculomotor nerve* has two major components: somatic motor and parasympathetic. The somatic motor portion of CN III innervates most of the extraocular musculature: dorsal rectus, medial rectus, ventral rectus, ventral oblique, and levator palpebrae superioris muscles. The parasympathetic component of CN III is responsible for pupillary constriction. The visual and pupillary constriction pathways are illustrated in Fig. 38.4. Damage to the oculomotor nucleus or CN III may lead to ventrolateral strabismus and/or a dilated pupil that is variably (depending on extent of the damage) responsive to light. Evaluation of the parasympathetic aspect of CN III function/dysfunction is done by shining a bright light into the eye and observing for pupillary constriction. Both pupils should constrict when a light is shone into one eye, with the eye being stimulated (direct) having stronger constriction than the opposite (indirect) eye. In this reflex, called the *pupillary light reflex*, the afferent information is carried via CN II, and the efferent response is mediated via CN III. It is important to use a strong light source when attempting to elicit a pupillary light reflex in a patient. Dogs and cats in a hospital surrounding often have high sympathetic tone, and using a weak light source on these patients may not be sufficient to effect pupillary constriction. The trochlear nucleus and its associated nerve, the *trochlear nerve* (CN IV), are responsible for innervation of the dorsal oblique muscle of the eye. This muscle prevents the outward (lateral) rotation of the dorsal aspect of the globe. Isolated deficits of this nucleus and nerve are rarely

TABLE 38.2 Cranial Nerves and Their Associated Functions

Cranial Nerve (CN)	Function/Innervation
CN I	Olfaction
CN II	Vision
CN III	• Somatic motor to most of the extraocular muscles (dorsal, medial, ventral rectus; ventral oblique; levator palpebrae superioris) • Parasympathetic innervation to pupil (pupillary light response)
CN IV	Somatic motor to dorsal oblique muscle of the eye
CN V	• Somatic motor to muscles of mastication • Somatic motor to tensor tympani muscle • Sensory to most of face
CN VI	Somatic motor to lateral rectus and retractor bulbi muscles (extraocular)
CN VII	• Somatic motor to muscles of facial expression • Somatic motor to stapedius muscle • Parasympathetic innervation to salivary glands (mandibular, sublingual)[a] and lacrimal, palatine, and nasal glands[b] • Sensory to inner pinna • Sensory (mechanoreception, thermal) and taste to rostral two-thirds of tongue (chorda tympani nerve)[c]
CN VIII	Vestibular function and hearing
CN IX-XI	• Somatic motor for laryngeal and pharyngeal function (nucleus ambiguus) • Parasympathetic innervation to salivary glands (parotid and zygomatic—CN IX)[d] • Parasympathetic innervation of viscera (CN X) • Sensory innervation of pharynx (CN IX and X) • Sensory and taste to caudal one-third of tongue (CN IX)
CN XII	Somatic motor to extrinsic and intrinsic tongue muscles

[a]Postganglionic axon in CN V, mandibular branch (after mandibular and sublingual ganglia).
[b]Postganglionic axon in CN V, maxillary branch (after pterygopalatine ganglion).
[c]Chorda tympani nerve joins lingual branch of mandibular branch of CN V near middle ear.
[d]Postganglionic axon in CN V, mandibular branch (after otic ganglion).

encountered in small animals; this CN is typically ignored in the cranial nerve examination of dogs and cats.

The motor nucleus of CN V in the pons and its associated efferent axons in CN V, the *trigeminal nerve,* are responsible for motor innervation of the muscles of mastication. Clinical evaluation of this CN is based primarily on visual and/or palpable evidence of masticatory muscle atrophy (Fig. 38.5). With bilateral dysfunction, the patient may not be able to close the mouth effectively. As mentioned, the sensory nucleus and tract of CN V is quite extensive. This is evaluated by checking for sensation around the face (Fig. 38.6 and Video 38.2). In addition, performing the corneal reflex evaluates the integrity of CNs V (sensory), VI, and VII (Fig. 38.7 and Video 38.3). The surface of the cornea is innervated by the ophthalmic branch of CN V. When the cornea is lightly touched with a moistened cotton applicator, the normal reflex is a blink (CN VII) and retraction of the globe (CN VI). CN VI, the *abducent nerve,* is derived from the abducent nucleus in the rostral medulla and provides somatic motor innervation to the retractor bulbi and lateral rectus muscles. Damage to this cranial nerve will impair the ability of the eyeball to retract (as in the corneal reflex) as well as to move laterally (when checking for physiologic nystagmus). CN VII, the *facial nerve,* innervates the muscles of facial expression and is derived from the facial nucleus in the medulla. This nerve is evaluated clinically by assessing for facial symmetry and performing the blink reflex, corneal reflex, and trigeminofacial reflex (Fig. 38.8). This latter reflex involves stimulating the maxillary region (CN V) and observing for a blink (CN VII). The facial nerve also supplies sensory innervation to the inner pinna, so this region can be lightly stimulated (e.g., hemostat tips) and the patient observed for a behavioral response.

CN VIII is the *vestibulocochlear nerve,* which carries the sensory modalities of hearing and balance. It is difficult to accurately test hearing during a neurologic examination; animals with normal hearing and normal mentation will turn to acknowledge loud or sudden noises. If clinically indicated, hearing is evaluated using an electrodiagnostic procedure called a *brainstem auditory evoked response test* (see p. 1318). The integrity of the vestibular system can be evaluated in several ways. A patient with normal vestibular function should not display a head tilt, ataxia, strabismus, or spontaneous (resting) nystagmus. Turning a patient's head to the side should induce a normal physiologic nystagmus directed horizontally with a fast phase in the direction of the head rotation. Dogs and cats are moved in various positions in an effort to elicit abnormal (positional) strabismus and nystagmus, both of which would indicate an abnormality with the vestibular system. Abnormalities of the vestibular system may be due to damage to the peripheral portion (inner ear) or the central portion (medulla and/or cerebellum) of this system (Fig. 38.9).

CNs IX *(glossopharyngeal nerve),* X *(vagus nerve),* and XI *(accessory nerve)* are considered together because they act as a group to innervate striated muscles of the larynx, pharynx, and esophagus. The cell bodies of these CNs are located in the nucleus ambiguus found in the ventrolateral medulla (Fig. 38.10). Laryngeal function cannot be evaluated in the awake patient, but dysfunction can be inferred from inspiratory stridor in dogs with bilateral laryngeal dysfunction. The ability to swallow normally can be deduced by performing the swallow or gag reflex. This test can be performed in one of two ways (Video 38.4). The first involves direct stimulation of the pharyngeal mucosa with a cotton applicator or a gloved finger (Fig. 38.11). The disadvantage of this method is that it is applicable only to

FIG. 38.3 The menace response is elicited by making a threatening gesture at the eye, which should induce a blink.

FIG. 38.5 Dog with severe masticatory muscle atrophy.

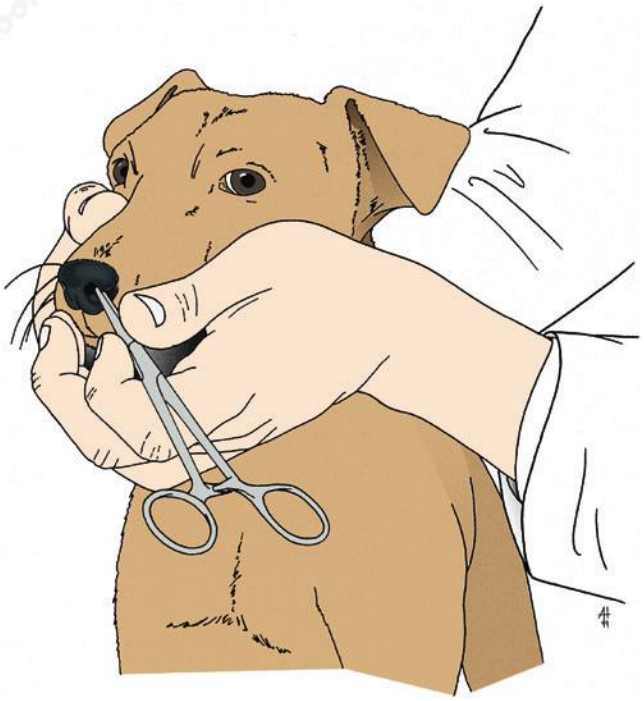

FIG. 38.6 The sensory portion of the trigeminal nerve (cranial nerve [CN] V) is tested by stimulating the nasal mucosa with a blunt instrument. Normal patients will pull their head away. (Modified from Dewey CW. *A Practical Guide to Canine and Feline Neurology*. 2nd ed. Hoboken, NJ: Wiley-Blackwell; 2008.)

FIG. 38.8 The palpebral or blink reflex is elicited by touching the skin medial or lateral to the eye. This will normally induce a blink.

FIG. 38.7 The corneal reflex is tested by touching the cornea with a cotton-tipped applicator moistened with saline. The normal response is retraction of the globe. (Modified from Dewey CW. *A Practical Guide to Canine and Feline Neurology*. 2nd ed. Hoboken, NJ: Wiley-Blackwell; 2008.)

FIG. 38.9 Dog with a positional ventrolateral strabismus. The patient was tentatively diagnosed with granulomatous meningoencephalomyelitis (see p. 1453).

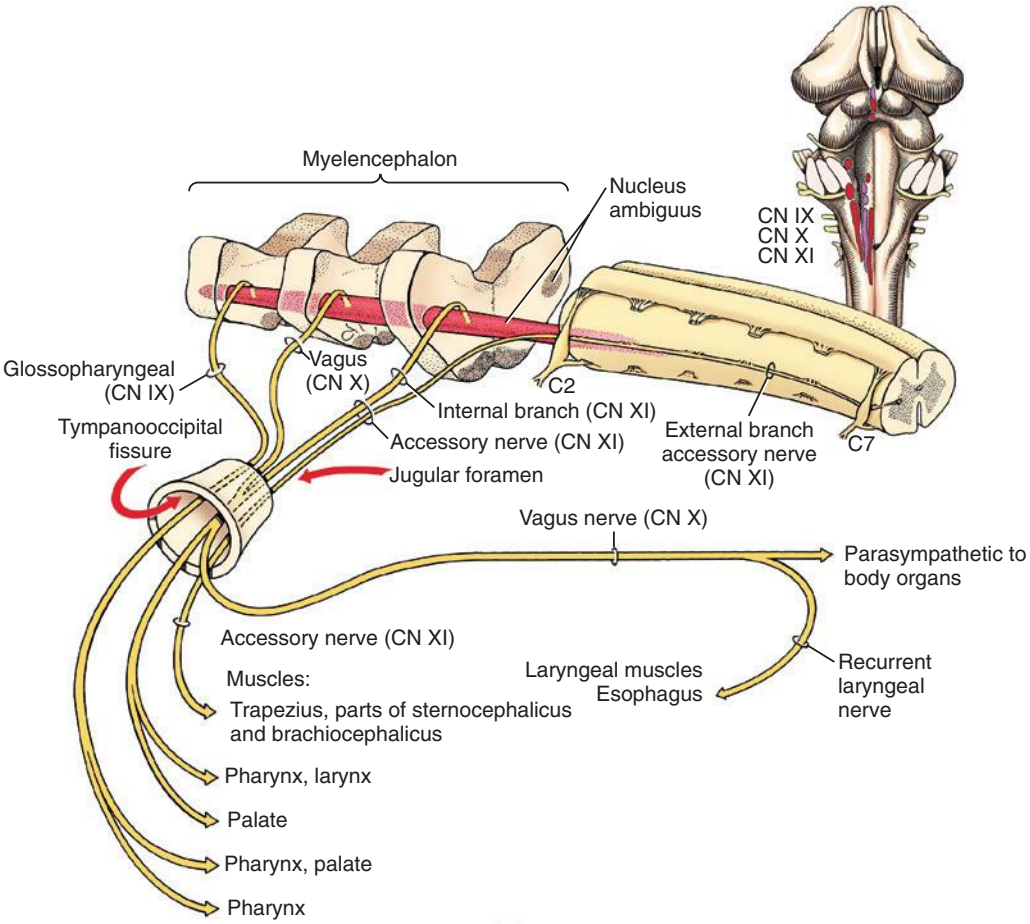

FIG. 38.10 Schematic illustration of the nucleus ambiguus and its innervations of the striated muscle of the larynx, pharynx, and esophagus. (From DeLahunta A. *Veterinary Neuroanatomy and Clinical Neurology*. 3rd ed. St. Louis: Saunders; 2009.)

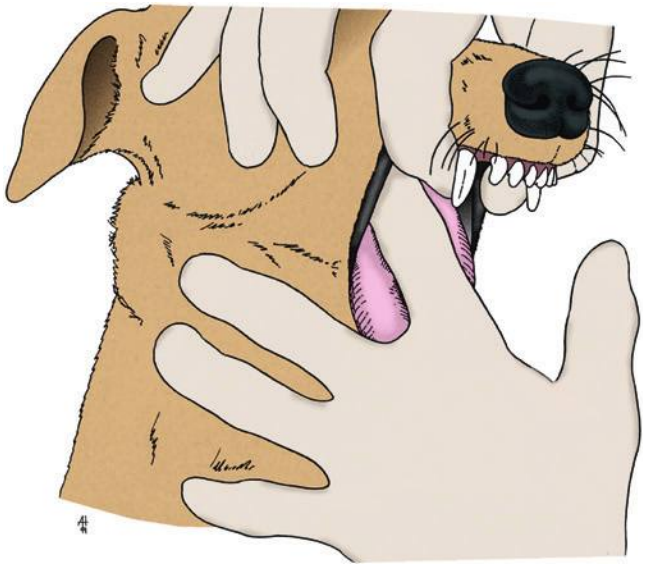

FIG. 38.11 The gag reflex is tested by touching the pharynx, which results in elevation of the palate and contraction of the pharyngeal muscles. (Modified from Dewey CW. *A Practical Guide to Canine and Feline Neurology*. 2nd ed. Hoboken, NJ: Wiley-Blackwell; 2008.)

very cooperative patients. The advantage is that the strength of the gag reflex can be directly felt (if a gloved finger is used). The other, safer (for the examiner) method, is to palpate the pharyngeal musculature externally, craniodorsal to the larynx (Fig. 38.12), and observe for a swallow from the patient. CN XII, the *hypoglossal nerve*, innervates the tongue musculature. This nerve originates from neuronal cell bodies in the hypoglossal nucleus located in the caudal medulla (Fig. 38.13). Tongue function can be evaluated by watching the patient drink water or lick his or her nose (dogs and cats often do this after the swallow/gag reflex, cats often lick their nose and swallow if the nose is rubbed by the examiner). In cooperative patients, the tongue can be grasped and directly observed for any atrophy (Fig. 38.14 and Video 38.5).

ATTITUDE POSTURE

Attitude refers to the position of the patient's eyes and head in relation to the body, whereas *posture* denotes the position of the body with respect to gravity. Abnormal attitudes are often manifested as a head tilt or a head turn. A head tilt, in which one ear is lower than the other, is a sign of unilateral vestibular dysfunction (Fig. 38.15). A head turn, in which the nose may be directed right or left but the ears are in the same horizontal plane (Fig. 38.16), is consistent with a forebrain lesion or cervical

syringomyelia (this curving of the spine is referred to as *scoliosis* or *torticollis*).

Abnormal postures are numerous and include a wide-based stance with the pelvic limbs or all four limbs (Fig. 38.17), which suggests abnormal proprioception; overflexion of the tarsal joints ("dropped" hocks) when standing, suggesting tibial nerve dysfunction; and holding up one limb ("root signature") as the result of spinal nerve irritation, among others. Some classic postures

FIG. 38.17 Dog with a wide-based pelvic limb stance due to cerebellar dysfunction. (Courtesy Dr. Joan Coates.)

described in the literature often cause confusion, probably because they are often discussed as if they would be difficult to discern from each other. The most common of these encountered clinically is the Schiff-Sherrington posture. This posture is characterized by rigid extension of the thoracic limbs (with preservation of thoracic limb function) accompanied by pelvic limb paresis or plegia. Increased extensor tone to the thoracic limbs is due to the interruption of a group of cells in the lumbar gray matter called *border cells*, or of those cells' cranially directed axonal processes (Fig. 38.18). These cells project their axons cranially to tonically inhibit the lower motor neurons (LMNs) of thoracic limb extensor muscles. When the border cells or their axons are disrupted as the result of a spinal cord lesion caudal to the cervical intumescence region, the thoracic limb extensors are "released" from this tonic inhibition. The thoracic limbs have excessive extensor tone (especially when the patient is in lateral recumbency), but there are no associated thoracic limb neurologic deficits. Most patients with Schiff-Sherrington posture have T3-L3 myelopathies, probably because this is a very common neuroanatomic presentation, and most are nonambulatory in the pelvic limbs. This posture is an anatomic phenomenon without prognostic significance. Dogs and cats with lower lumbar spinal cord lesions can also display this posture as the result of interruption of the border cells directly (they are located in the dorsolateral ventral gray matter from L1–L7 spinal cord segments). As there is no brain involvement with this phenomenon, it should not be confused with other postures that display thoracic limb hyperextension (i.e., decerebrate and decerebellate rigidity).

Decerebrate rigidity (Fig. 38.19) is a posture caused by a severe brainstem lesion; it is characterized by rigid extension of all four limbs and often includes *opisthotonus* (dorsiflexion of the head and neck). Because of the location of the causative lesion, dogs

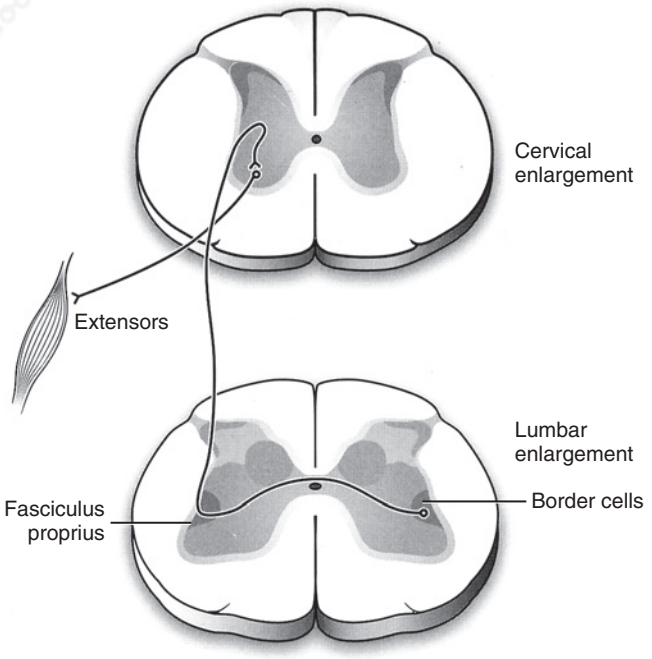

FIG. 38.18 The ascending inhibitory pathway to thoracic limb lower motor neurons, interruption of which leads to the Schiff-Sherrington phenomenon. (Modified from Burke MJ, Colter SB. A practical review of canine and feline spinal cord anatomy. *Prog Vet Neurol.* 1990;1:358–370.)

FIG. 38.19 Cat exhibiting decerebrate rigidity caused by a brainstem lesion.

and cats with decerebrate rigidity typically have severe disturbances of consciousness (i.e., stupor or coma). Decerebellate rigidity is less commonly encountered and is due to acute cerebellar damage. This posture is characterized by rigid extension of the thoracic limbs and flexion of the pelvic limbs. With isolated cerebellar involvement, there should be no impairment of consciousness. Because of the anatomic proximity of the cerebellum and brainstem, it is more common to encounter patients with lesions impairing both (e.g., cerebellomedullary angle lesions) than to encounter patients with purely cerebellar dysfunction. These patients may display a posture with characteristic features of both decerebrate and decerebellate rigidity. In such scenarios, it is important to realize that there is no clinical utility in expecting a patient to adhere to a classic posture when the neuroanatomic localization has already been made.

GAIT

Generation of gait in dogs and cats is primarily dependent on brainstem centers. Unlike in primates, the forebrain has minimal input on their gait generation, but it does provide purposefulness of movement. The main regions of the brainstem and their associated tracts thought to be important for gait generation (Fig. 38.20) are the red nucleus and rubrospinal tract, the pontine reticular formation and the pontine reticulospinal tract, and the medullary reticular formation and the medullary reticulospinal tract. For a coordinated gait to be sustained, proprioceptive information regarding limb position is constantly delivered to these gait-generating nuclei during motion (primarily via the cerebellum, which receives this information via spinocerebellar tracts). In addition, a balanced and coordinated gait requires normal function of the peripheral and central vestibular systems. Observation of an animal's gait often reveals a wealth of information regarding lesion localization. In addition to looking for directionality to the patient's gait (e.g., circling in one direction), other abnormalities of the gait itself, such as lameness, toe-dragging, ataxia, and paresis/plegia, may be noticed. In most cases, lameness is due to orthopedic disease. However, some neurologic disorders manifest as lameness, especially early in the disease process. These include irritation of a nerve root due to disk extrusion, resulting in lameness or holding up a limb (i.e., "root signature," which is most common in thoracic limbs), lameness of one thoracic limb due to a malignant nerve sheath tumor, and unilateral or bilateral pelvic limb lameness due to degenerative lumbosacral stenosis and compression of the cauda equina nerves.

Ataxia invariably points to neurologic disease and is often characterized as sensory ataxia, vestibular ataxia, or cerebellar ataxia (Box 38.2). Sensory ataxia is due to interference with ascending spinal cord proprioceptive pathways and is manifested by a swaying gait. The patient with sensory ataxia may also drag his or her toes. An overall clumsy nature to the gait is apparent, and the patient may actually fall when turning. Vestibular ataxia and cerebellar ataxia may be difficult to differentiate in some patients because the vestibular system is closely associated with the cerebellum. However, if such a patient has other clear evidence of central vestibular dysfunction, such differentiation is superfluous. With unilateral peripheral or central vestibular lesions, animals tend to display a head tilt and to lean or fall toward the side of the head tilt. These patients tend to display general ataxia of all four limbs, but the direction to which the patient falls or leans is consistent. Dogs and cats with bilateral peripheral vestibular dysfunction may display a very characteristic gait, characterized by wide, side-to-side head excursions while ambulating. Cerebellar ataxia also affects all four limbs. In addition to a clumsy gait, evidence of hypermetria or exaggerated limb protraction is often noted while ambulating. This "high-stepping" gait is characteristic of cerebellar dysfunction. When stationary, some of these patients may display head tremors, especially if offered a treat or some other enticement (intention tremor), and/or a whole-body sway from side to side (titubation). Dogs and cats with cerebellar lesions may also display obvious signs of vestibular dysfunction (e.g., strabismus, nystagmus, head tilt). The cerebellum is intimately tied to the vestibular system, and

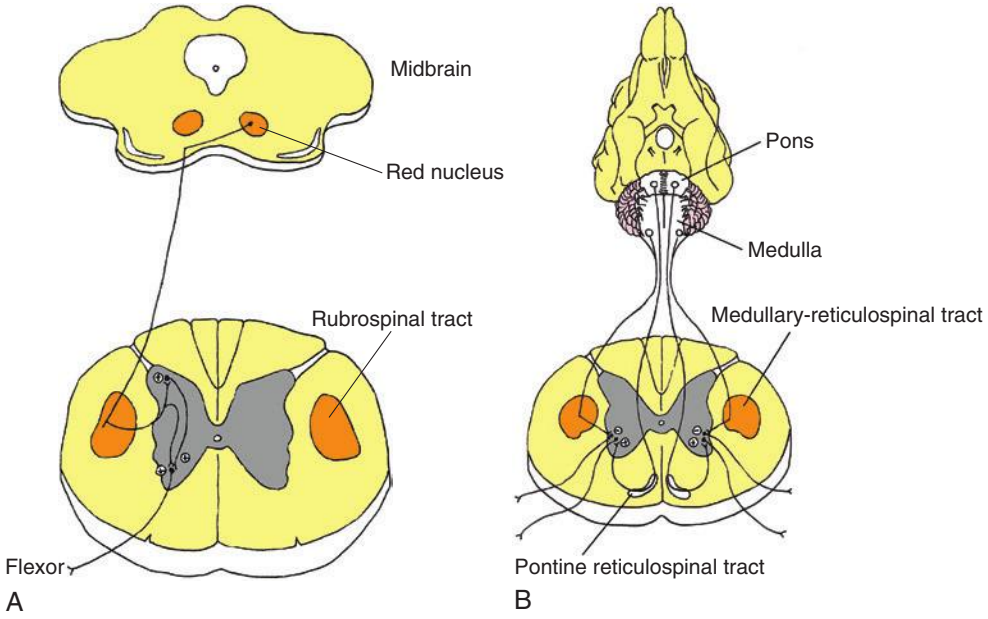

FIG. 38.20 Important gait-generating brainstem nuclei and tracts in dogs and cats. (A) The red nucleus and rubrospinal tract. (B) The pontine and medullary reticulospinal tracts. BOX 38.2 Characterization of Ataxia in Dogs and Cats

Sensory Ataxia

- Due to interference with ascending spinal cord proprioceptive pathways
- Manifested as a swaying gait
- Toe dragging may be evident
- Clumsy gait
- May fall when turning

Vestibular Ataxia

- Head tilt often present
- Leaning or falling to one side (side of head tilt, if present)
- General ataxia of all four limbs
- Wide, side-to-side head excursions with bilateral peripheral vestibular dysfunction

Cerebellar Ataxia

- Hypermetria often evident, in addition to clumsy gait
- Head tremors and/or whole-body sway (titubation) when stationary
- Often have signs of vestibular dysfunction

the vestibular nuclei in the medulla are directly ventral to the cerebellum. It is very common to observe animals with gaits suggestive of cerebellovestibular dysfunction.

Paresis denotes a partial loss of voluntary movement, whereas *plegia* (or paralysis) means a complete loss of voluntary motion. The terms paresis and plegia do not by themselves connote anything regarding muscle tone; nonetheless, clinicians tend to confuse muscle flaccidity with paresis. LMN paresis/plegia is typified by muscle flaccidity and poor to absent spinal reflexes. Patients have sustained damage to the LMNs and/or their axons that directly innervate the muscles responsible for walking (e.g., quadriceps muscles). Upper motor neuron (UMN) paresis/plegia is typified by normal or exaggerated muscle tone and spinal reflexes. These animals have sustained damage to the UMN white matter tracts descending from the brainstem that "tell" the LMNs what to do during gait generation. In either situation, paresis or plegia refers only to a decreased ability or inability to ambulate. In addition, the ability to perceive pain (i.e., nociception) is not implied in the description of gait. This is a separate part of the neurologic examination. Prefixes are added to the terms paresis or plegia to fully describe a patient's gait. *Paraparesis* and *paraplegia* are terms used to describe animals with pelvic limb weakness and lack of voluntary motor ability, respectively. For animals with all four limbs involved, the terms *tetraparesis* and *tetraplegia* are used (some prefer *quadriparesis* and *quadriplegia*, respectively). When one limb is involved (e.g., brachial plexus injury), the terms *monoparesis* and *monoplegia* are used. The full description of gait in a paretic patient includes a subjective assessment of whether a patient can walk unassisted. This is sometimes open to interpretation. The author considers a patient that cannot walk more than a few steps without falling over to be nonambulatory. Such a patient would be described as nonambulatory paraparetic.

POSTURAL REACTIONS

Postural reactions evaluate the pathways involved in gait-proprioceptive and motor pathways. General proprioception is conceptually divided into conscious and unconscious proprioception and refers to position sense, or the ability for an animal to judge where his or her body parts are in space and in relation to the rest of the body. Although an oversimplification, *conscious proprioception* is conveyed by the dorsal column/medial lemniscus pathways (i.e., fasciculus gracilis, fasciculus cuneatus, spinomedullary tracts) (Fig. 38.21) and represents position sense that is

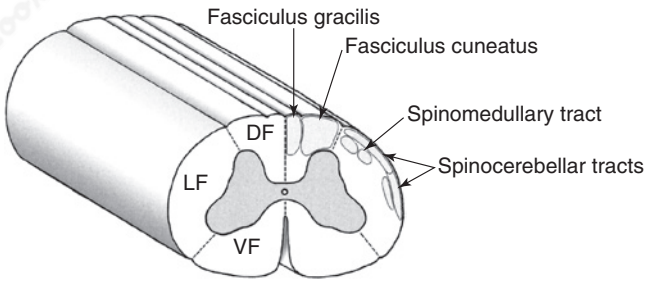

FIG. 38.21 Ascending proprioceptive pathways in the spinal cord. *DF,* Dorsal funiculus; *LF,* lateral funiculus; *VF,* ventral funiculus. (Modified from Dewey CW. *A Practical Guide to Canine and Feline Neurology*. 2nd ed. Hoboken, NJ: Wiley-Blackwell; 2008.)

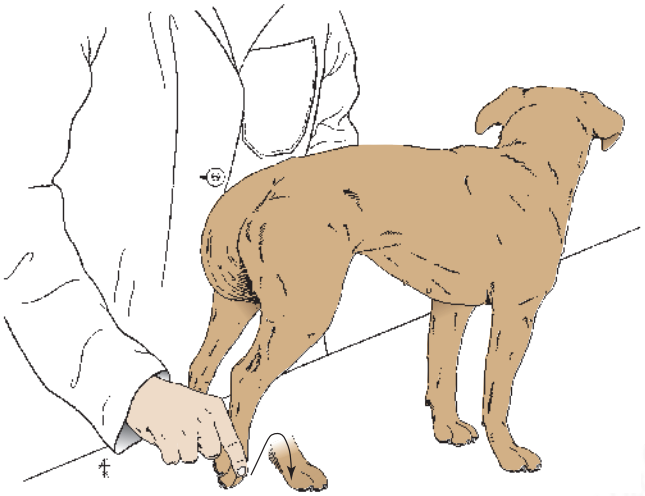

FIG. 38.22 Proprioceptive positioning is evaluated with the patient supported in a standing position. The dorsal surface of the paw is placed on the floor. The patient should immediately replace the foot to a normal position. (Modified from Dewey CW. *A Practical Guide to Canine and Feline Neurology*. 2nd ed. Hoboken, NJ: Wiley-Blackwell; 2008.)

perceived at the cerebral level; *unconscious proprioception* is conveyed mainly by spinocerebellar pathways (i.e., dorsal and ventral spinocerebellar tracts, cuneocerebellar tract, rostral spinocerebellar tract) and represents position sense that is processed by the cerebellum, without conscious involvement. Conscious proprioceptive pathways are represented primarily in the contralateral cerebral cortex, whereas unconscious pathways are essentially ipsilateral. Conscious proprioception is best evaluated with the animal in a standing position, whereas unconscious proprioception is best evaluated with the animal moving. Isolated conscious proprioceptive deficits with normal gait (i.e., normal unconscious proprioception) is a hallmark of forebrain disease, whereas isolated unconscious proprioceptive deficits with normal proprioceptive positioning responses (i.e., normal conscious proprioception) are characteristic of cerebellar disease. In most patients with brainstem and spinal cord lesions, a combination of conscious and unconscious proprioception (general proprioception) compromise is expected.

A number of postural reaction tests can be performed while the neurologic examination is conducted. These various tests include proprioceptive positioning (Fig. 38.22), tactile placing (Fig. 38.23), hopping (Fig. 38.24), hemiwalking (Fig. 38.25), and

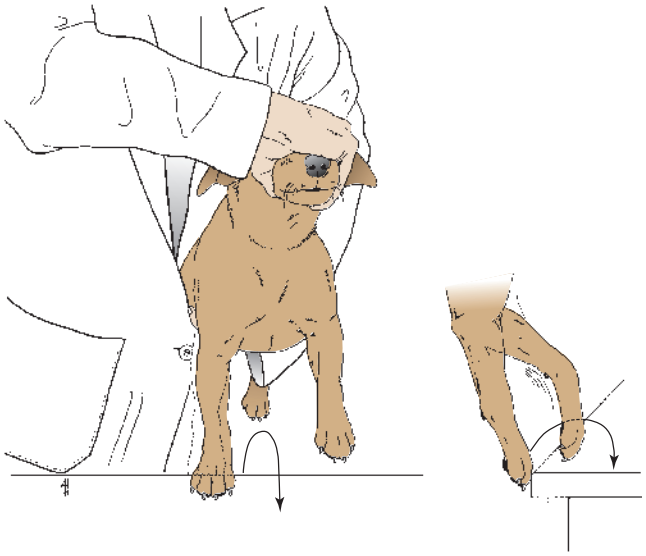

FIG. 38.23 Tactile placing is tested by covering the patient's eyes and moving the patient toward the edge of the table. Normal patients will place their paws on the table as soon as they contact the table edge. (Modified from Dewey CW. *A Practical Guide to Canine and Feline Neurology*. 2nd ed. Hoboken, NJ: Wiley-Blackwell; 2008.)

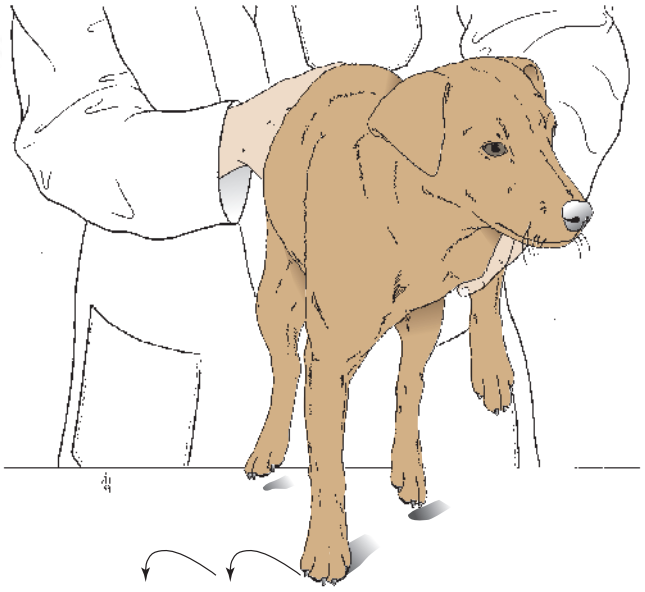

FIG. 38.24 The hopping response is tested by holding the patient in a way that most of the weight is borne on one limb. The patient is moved laterally. Normal animals will hop briskly and symmetrically (hopping is performed as well bilaterally). (Modified from Dewey CW. *A Practical Guide to Canine and Feline Neurology*. 2nd ed. Hoboken, NJ: Wiley-Blackwell; 2008.)

wheelbarrowing (Fig. 38.26). Because these tests all evaluate proprioception, it is not necessary to perform all of them on each patient. For each of these tests, it is important to evaluate for asymmetry, as well as for obvious deficiencies in their execution by the patient. *Proprioceptive placing* (Video 38.6) entails supporting the patient (to avoid stimulation of the vestibular system) while placing one paw at a time over the

FIG. 38.25 Hemiwalking is tested by lifting the limbs on one side and moving the patient laterally. Normal animals will hop briskly and symmetrically. (Modified from Dewey CW. *A Practical Guide to Canine and Feline Neurology*. 2nd ed. Hoboken, NJ: Wiley-Blackwell; 2008.)

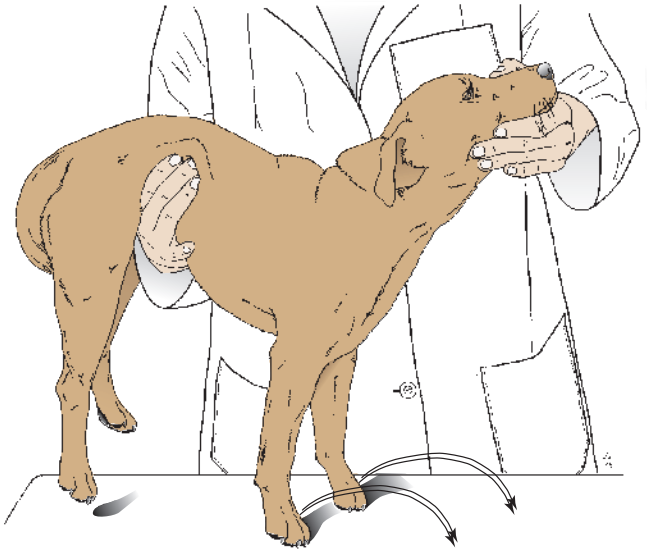

FIG. 38.26 Wheelbarrowing is tested by supporting the patient under the abdomen so that the pelvic limbs do not touch the ground and then moving the patient forward. Normal patients will walk briskly without knuckling and without evidence of hypermetria. (Modified from Dewey CW. *A Practical Guide to Canine and Feline Neurology*. 2nd ed. Hoboken, NJ: Wiley-Blackwell; 2008.)

dorsal surface; the normal reaction to this maneuver is rapid replacement of the paw to a normal position. Cats and small breed dogs often resist this technique, tending to rapidly withdraw the limb every time the examiner attempts to grasp the paw; in these patients, tactile placing and hopping may be more informative. *Tactile placing* is performed by covering the patient's eyes and moving his or her paws to the edge of a table; the normal response is rapid placement of the paw on top of the table. This technique involves picking up the pet, so it is generally performed on small dogs and cats. *Hopping* is performed by holding the animal so that most of his or her weight is borne on the limb being evaluated. The patient is then moved laterally. The normal response is a brisk hopping motion to the side to which the animal is moved. *Hemiwalking* involves supporting one side of the patient and having the patient walk laterally with the thoracic and pelvic limbs of one side. The thoracic limb is typically a bit faster than the pelvic limb, but a quick and organized hopping motion is expected. Normal animals have difficulty hopping and hemiwalking in a medially oriented direction, so these tests should be performed only with the patient being directed laterally. *Wheelbarrowing* is performed by supporting the patient under the abdomen so that the pelvic limbs are non–weight-bearing and moving the patient forward with the head in an extended position. This test is most useful in patients with subtle thoracic limb proprioceptive deficits, most notably those with caudal cervical myelopathy. In this scenario, many such patients will appear to "float" (a very protracted swing phase of the gait) with the thoracic limbs once the ability to compensate visually is removed.

SPINAL REFLEXES

Spinal reflexes are used to assess the integrity of sensory and motor components of the particular reflex, in addition to the influence of descending UMN pathways. Two types of spinal reflexes are evaluated during the neurologic examination: *withdrawal reflex* and *tendon (stretch) reflex*. The former is a polysynaptic reflex elicited by the application of a noxious stimulus to a digit. The latter is essentially a monosynaptic reflex elicited by tapping a taut tendon or ligament with the muscle of interest in extension. The author has not found numeric grading of reflexes to be of clinical value; rather, referring to reflex strength as absent, weak (present but diminished in comparison with normal), normal, or exaggerated has greater clinical utility. *Clonus* refers to a repetitive flexion and extension of a joint following a single stimulus and is an indication of chronic UMN disease. Absent to weak spinal reflexes are indicative of LMN disease, whereas normal to exaggerated spinal reflexes are consistent with UMN disease. The finding of normal to exaggerated spinal reflexes must be evaluated in the context of the remainder of neurologic examination findings. Excited patients often display exaggerated patellar reflexes; in the absence of any other neurologic deficits, this should be regarded as normal. Lack of a patellar reflex in one or both pelvic limbs in older dogs (>10 years old) is a common age-related phenomenon; in the absence of any other neurologic deficits, this finding has little to no clinical significance.

Thoracic limb reflexes routinely tested include the withdrawal reflex, the biceps reflex, and the triceps reflex. As has been mentioned, the withdrawal reflex is a polysynaptic reflex for which the normal response is flexion of all joints of the limb in response to a mild noxious stimulus (Video 38.7). The *biceps reflex* is a stretch reflex that evaluates the integrity of the musculocutaneous nerve and the C6–C8 spinal cord segments. This is performed with the patient in lateral recumbency and the thoracic limb of interest fully extended and pulled backward (Fig. 38.27). The index finger is placed on the tendon of insertion of the biceps muscle, and the finger is tapped with a pleximeter.

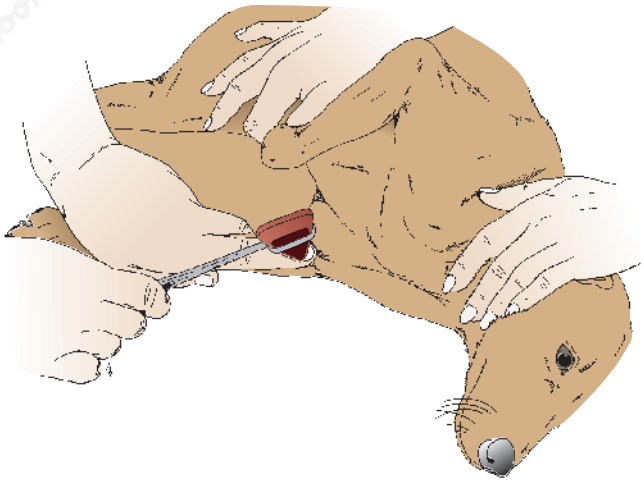

FIG. 38.27 The biceps reflex is elicited by striking the examiner's finger placed over the biceps tendon just proximal to the elbow. (Modified from Dewey CW. *A Practical Guide to Canine and Feline Neurology*. 2nd ed. Hoboken, NJ: Wiley-Blackwell; 2008.)

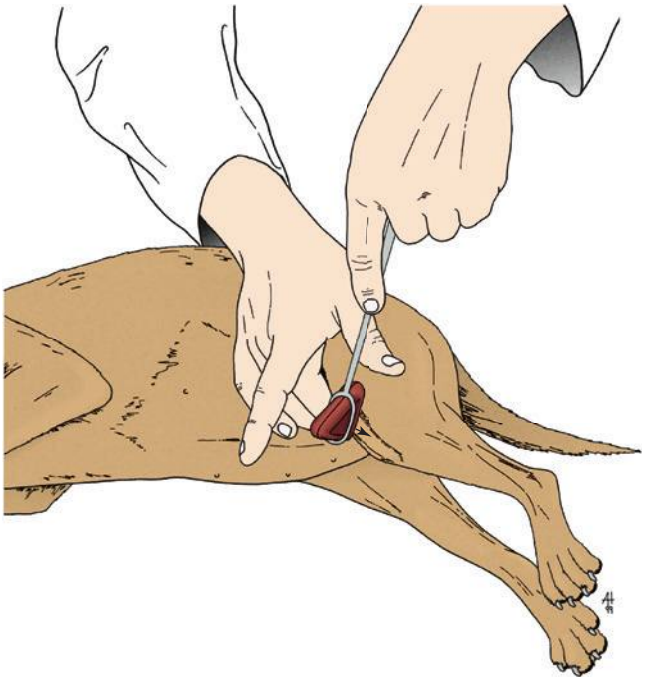

FIG. 38.29 The patellar reflex is elicited by percussing the patellar ligament between the patella and the tibial tuberosity. (Modified from Dewey CW. *A Practical Guide to Canine and Feline Neurology*. 2nd ed. Hoboken, NJ: Wiley-Blackwell; 2008.)

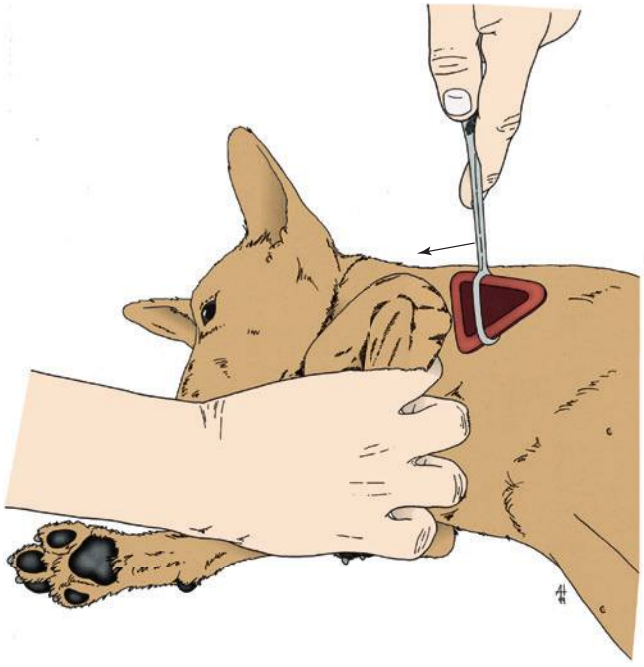

FIG. 38.28 The triceps reflex is elicited by percussing the triceps tendon just proximal to the olecranon. (Modified from Dewey CW. *A Practical Guide to Canine and Feline Neurology*. 2nd ed. Hoboken, NJ: Wiley-Blackwell; 2008.)

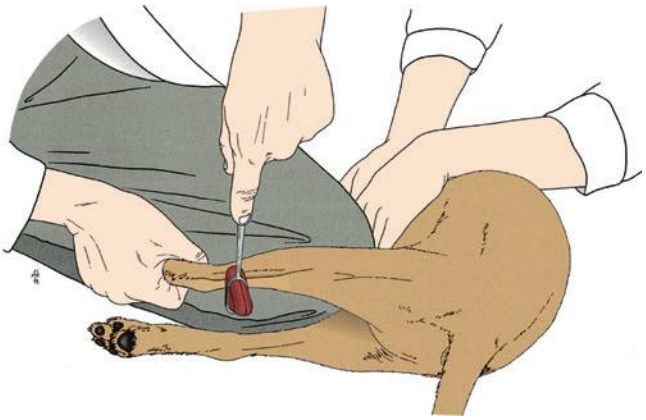

FIG. 38.30 The gastrocnemius reflex is elicited by percussing the gastrocnemius tendon just proximal to the calcaneus. (Modified from Dewey CW. *A Practical Guide to Canine and Feline Neurology*. 2nd ed. Hoboken, NJ: Wiley-Blackwell; 2008.)

The normal response is contraction of the muscle, which can be appreciated along the length of the brachium. The *triceps reflex* tests the integrity of the radial nerve and spinal cord segments C7–T1. This reflex is often difficult to appreciate in dogs and cats, so its absence should not be overinterpreted. The shoulder is flexed, and the triceps tendon is struck medially with a pleximeter (Fig. 38.28). The normal response is contraction of the entire triceps muscle mass (Video 38.8).

Pelvic limb reflexes typically assessed include the withdrawal reflex, the patellar reflex, and the gastrocnemius reflex. As with the thoracic limb, the *pelvic limb withdrawal reflex* is a polysynaptic reflex in which all joints of the pelvic limb flex in response to a mild noxious stimulus. The *patellar reflex* is a tendon reflex in which the patellar ligament is tapped (with the stifle joint in some degree of flexion) and extension of the lower limb (crus) is observed (Fig. 38.29 and Video 38.9). The patellar reflex assesses the integrity of the femoral nerve and the L4–L6 spinal cord segments. The *gastrocnemius reflex* (Fig. 38.30) is performed by tapping the gastrocnemius tendon with the stifle extended and the hock flexed. A normal response is contraction of the caudal

FIG. 38.31 The panniculus or cutaneous trunci reflex is evaluated by lightly pinching the skin just lateral to the spine, starting over the lumbosacral region and proceeding cranially. The normal response is a bilateral contraction of the cutaneous trunci muscle, resulting in a twitch of the skin over the thorax and abdomen.

FIG. 38.32 Gently stroking or pinching the perineum tests the perineal reflex. The normal response consists of flexion of the tail and contraction of the external anal sphincter.

thigh musculature (Video 38.10). This tendon reflex assesses the integrity of the sciatic nerve and the L6–S2 spinal cord segments.

Other spinal reflexes routinely assessed are the cutaneous trunci reflex and the perineal reflex. The *cutaneous trunci (panniculus) reflex* evaluates the integrity of the lateral thoracic nerve, the C8-T1 spinal cord segments, and the sensory input to the spinal cord (dorsal nerve roots) in the dermatomes being stimulated. The skin is pinched lightly with hemostats over the dorsum (Fig. 38.31), and the normal response is contraction of the cutaneous trunci musculature, manifested as skin twitch over the thorax and abdomen (Video 38.11). The contraction is bilateral. An obvious cutoff point in this reflex along the spine in patients with spinal cord disease supports a lesion in the spinal cord one to four segments cranial to the cutoff (spinal cord segments are typically cranial to their associated spinal nerves). This reflex usually cannot be elicited in the lumbosacral and cervical regions and is often difficult to appreciate in normal cats. The *perineal (anal) reflex* assesses the integrity of the sacral spinal cord (S1–S3) segments and various branches of the pudendal nerve. The skin around the perineum is lightly touched, eliciting contraction of the anal sphincter (Fig. 38.32 and Video 38.12). This stimulation also typically elicits tail flexion, which evaluates the integrity of the coccygeal (caudal) spinal cord segments and associated nerves.

The *crossed extensor reflex* is an abnormal reflex that indicates the presence of a UMN lesion located cranial to the spinal cord segments responsible for the reflex of interest. With the patient in lateral recumbency, a digit of one limb is stimulated (e.g., finger pinch) to elicit a withdrawal reflex. A positive crossed extensor reflex is observed if the opposite limb extends as the other flexes. This represents an UMN release phenomenon. This action should be normally inhibited when the patient is in lateral recumbency. *Spinal shock* refers to a transient lack of reflex activity caudal to a severe spinal cord lesion; this phenomenon of hypotonia and hyporeflexia with lesions that should cause UMN signs is uncommon and short-lived in dogs and cats compared with humans. A form of this phenomenon may frequently be observed in dogs with spinal cord infarction (fibrocartilaginous embolic myelopathy) in the T3–L3 spinal cord region. These

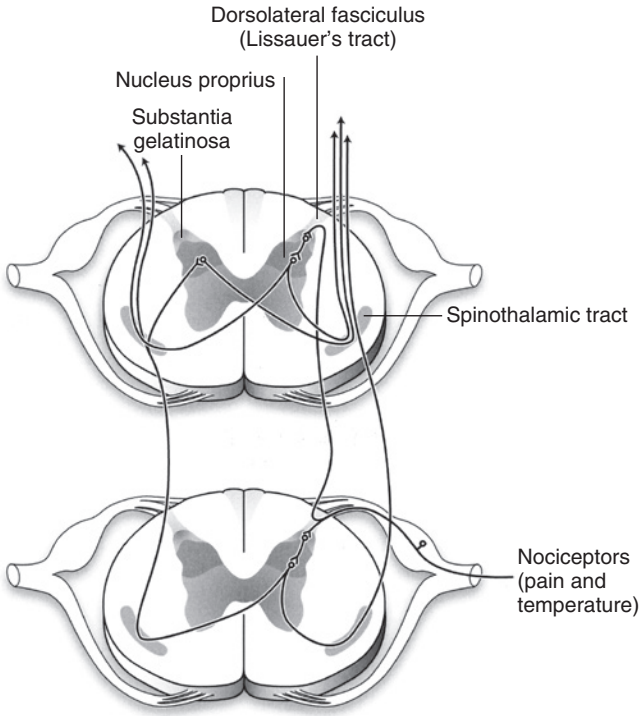

FIG. 38.33 Schematic illustration of the classic spinothalamic tract for nociception in the dog and cat. (Modified from Burke MJ, Colter SB. A practical review of canine and feline spinal cord anatomy. *Prog Vet Neurol.* 1990;1:358–370.)

patients typically exhibit UMN signs with the exception of poor withdrawal reflexes; the withdrawal reflex returns to normal within 72 hours.

PAIN SENSATION (NOCICEPTION)

The modality of nociception or pain perception is transmitted from the periphery to the brain via a number of spinal cord pathways. The classic, contralateral spinothalamic pathway (Fig. 38.33) of people is not considered to be as contralateral (more of a multisynaptic bilateral pathway) in dogs and cats;

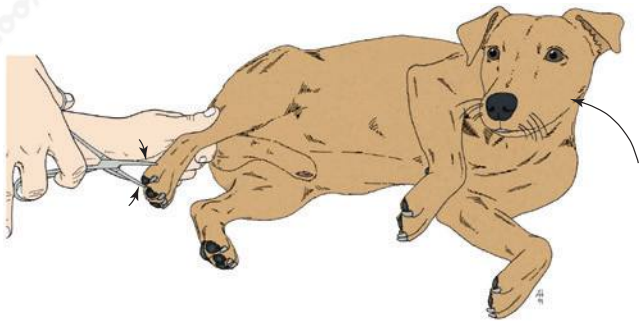

FIG. 38.34 Testing for deep pain perception is performed by using a hemostat to pinch the digit. A conscious response, such as crying or turning the head, indicates perception of deep pain. (Modified from Dewey CW. *A Practical Guide to Canine and Feline Neurology*. 2nd ed. Hoboken, NJ: Wiley-Blackwell; 2008.)

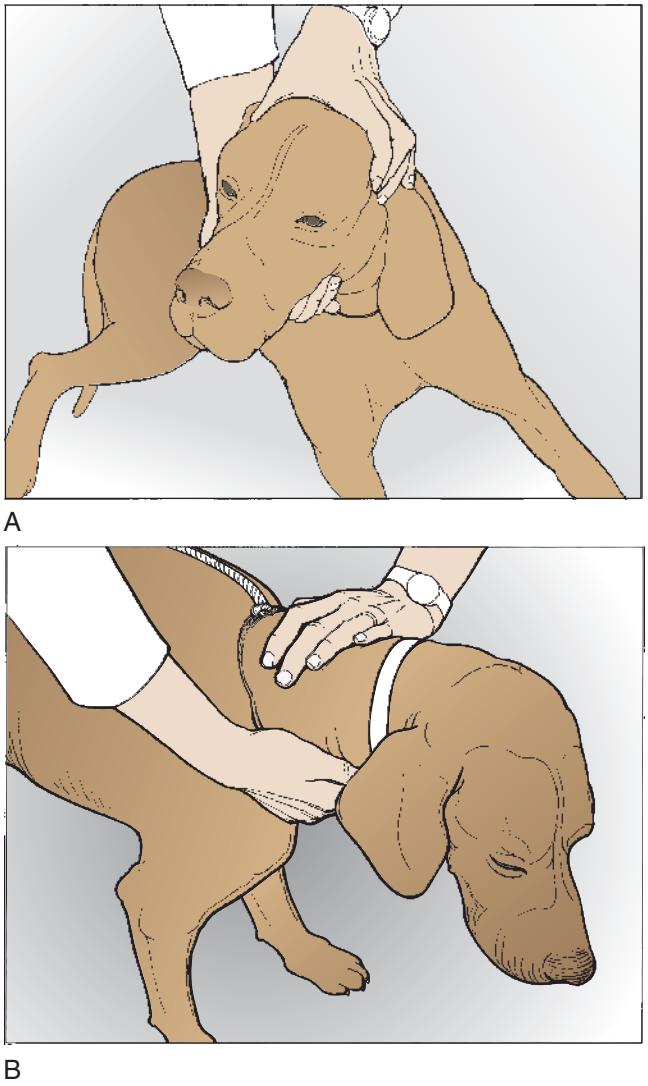
however, there are numerous dogs and cats with hemineglect syndrome in which the patient fails to acknowledge noxious stimuli applied to the side of the body opposite to the side of a cerebral lesion. Other pain-transmitting pathways considered important in dogs and cats include the spinocervicothalamic, spinoreticular, spinomesencephalic, and propriospinal pathways. For the veterinarian, two areas of nociceptive function/dysfunction are of interest: (1) the presence or absence of normal pain perception ability and (2) the presence or absence of excessive pain perception (e.g., hyperesthesia, paresthesia). It is important to realize that this aspect of the neurologic examination involves the examiner's interpretation of the patient's *perception* of pain. Perception infers that there should be a behavioral response to whatever stimulation the examiner applies. Reflex activity may well be elicited by the application of a noxious stimulus, but this is *not* what is being assessed at this point in the neurologic examination. If a patient's spinal cord is physically or physiologically transected at the level of T13–L1, pinching the digits of the pelvic limbs will elicit a withdrawal reflex because all necessary components of that reflex are still intact. However, nociceptive information will not traverse the lesion site and will not reach the cerebrum, so there will be no conscious reaction (e.g., attempting to bite, looking back at the examiner, vocalization).

Superficial pain refers to sharp, well-localizable, "fast" pain that is conveyed in the spinal cord primarily by larger, more rapidly conducting axons (e.g., type A-delta). *Deep pain* refers to dull, less-localizable, "slow" pain that is conveyed by smaller, less rapidly conducting axons (e.g., type C). These categories do not represent separate pathways, and the distinction between the degrees of stimulus needed to achieve an obvious behavioral response qualifying as a superficial or deep pain response is subjective and arbitrary. In practical terms, if a patient exhibits a behavioral response to a light skin pinch on the digit with your fingertips, both superficial and deep pain sensation can be judged to be intact. The lack of such a response when a digit is clamped with an instrument such as a hemostat (Fig. 38.34) suggests a more profound injury to the nociceptive–transmitting spinal cord pathways and typically a less favorable prognosis.



A

B

FIG. 38.35 Palpation of the (A) head and (B) neck for evidence of hyperesthesia. (Modified from Dewey CW. *A Practical Guide to Canine and Feline Neurology*. 2nd ed. Hoboken, NJ: Wiley-Blackwell; 2008.)

The entire spinal region and head should be palpated for areas of excessive pain response. For the thoracic and lumbar spine, this is done by pushing on either side of the dorsal spinous processes with thumb and forefinger. For the cervical region, palpating the ventral aspect of the vertebrae is the most sensitive method for finding areas of hyperesthesia. Evidence of head pain is typically elicited in patients with intracranial space-occupying or inflammatory diseases when the head is lightly squeezed above the zygomatic arch region (Fig. 38.35).

39

Surgery of the Brain

GENERAL PRINCIPLES AND TECHNIQUES

DEFINITIONS

Creating a defect in the skull to access the brain is a **craniotomy.** Standard craniotomies typically performed in dogs and cats include **lateral** or **rostrotentorial craniotomy, transfrontal craniotomy,** and **suboccipital craniotomy. Intracranial pressure (ICP)** is the pressure exerted by tissues and fluid within the cranial vault and is normally in the range of 5 to 12 mm Hg in dogs and cats. **Cerebral perfusion pressure (CPP)** represents the forward (i.e., arterial to venous) driving pressure that is the main determinant of brain blood flow and hence brain oxygenation and nutrient support. **Autoregulation** refers to the intrinsic ability of the brain to maintain a constant ICP within the mean arterial pressure (MAP) extremes of 50 to 150 mm Hg. However, significant variability has been noted between individuals, and these numbers serve only as a guideline. **Pressure autoregulation** links brain vascular tone with systemic blood pressure (when MAP increases, vasoconstriction in brain blood vessels prevents an ICP increase and vice versa), whereas **chemical autoregulation** refers to the direct responsiveness of brain vasculature to the partial pressure of carbon dioxide ($PaCO_2$) in arterial blood (hypercapnia leads to brain vascular dilation and vice versa). **Compliance** is a change in volume per unit change in pressure within the intracranial compartment and reflects the ability of that compartment to accommodate excess volume (e.g., mass, hematoma) by shifting fluids within the compartment.

GENERAL CONSIDERATIONS

The three main types of craniotomy are sometimes combined to provide increased exposure to parts of the brain for various conditions; they may be modified when necessary. For example, bilateral rostrotentorial craniotomies may be required at times; this may also involve removing the top of the skull. Increased ventral exposure may be needed in some cases during a rostrotentorial craniotomy; this may require resection of part of the zygomatic arch and/or the coronoid process of the mandible. When working in the caudal fossa region, it may be necessary to extend a suboccipital craniotomy laterally by sacrificing one of the transverse sinuses. Sometimes more room is needed caudally in this approach, which is achieved by partial or complete removal of the dorsal arch of the atlas (C1). Ventral approaches to the brain are seldom performed in dogs and cats and therefore will not be discussed in this chapter. The relationship between ICP and CPP and MAP is as follows: CPP = MAP – ICP. Compliance decreases as intracranial volume increases, as is shown in Fig. 39.1. Once an intracranial volume is reached that is close to the limit of the compliance ability of the intracranial compartment, even small increases in intracranial volume (e.g., brain edema, brain vasodilation from anesthesia) will lead to large increases in ICP.

Preoperative Management

The specifics of preoperative management for the brain surgery patient depend to a large degree on the underlying disease process. With increased availability of magnetic resonance imaging (MRI) in dogs and cats, the repertoire of surgical brain disorders in these species has expanded (see also Chapter 14). Patients with disorders typified by slow-growing mass lesions (e.g., brain tumors, intracranial arachnoid cysts [IACs]) will often benefit from low doses of oral prednisolone (e.g., 0.5 mg/kg every 12 hours) in the time period before surgery is scheduled and for some time afterward. Prednisolone alleviates edema surrounding the lesion and typically improves the patient's neurologic status dramatically within 24 to 48 hours. Glucocorticoids should not be given as an emergency treatment for acute brain injury (particularly the "high-dose methylprednisolone" protocol) because they have repeatedly failed to demonstrate any statistically significant benefit in terms of central nervous system (CNS) trauma, and they have the potential for serious adverse gastrointestinal effects.

Adequate fluid support must be provided before anesthesia is given. Overzealous intravenous (IV) fluid administration is thought to exacerbate brain edema, especially in trauma patients; however, fluid restriction is strictly contraindicated. The response of the vasculature to hypotension is vasodilation. In a closed vault such as the cranium, the result is an increase in space taken up by the vasculature. The patient with brain pathology may have additional elevations in ICP caused by this vasodilatory response to hypotension. Conversely, marked hypertension causes an increase in cerebral blood volume and promotes cerebral edema. Therefore the goal is to keep blood pressure within the normal range, avoiding hypotension and marked hypertension. Patients that present with an increased ICP often have systemic hypertension: an indication that efforts to reduce ICP are necessary. Normal saline is the fluid of choice for brain surgery. Because of the blood-brain barrier, osmotic pressure, not oncotic pressure, is the driving force for movement of water out of the vasculature and into the interstitial and intracellular fluid compartments of the brain. In other words, sodium is of vital importance. To minimize brain edema, serum tonicity should be maintained. This is best done by using normal saline and rechecking serum sodium levels when diuretics such as mannitol are used. In acute brain injury patients, hypertonic saline and/or colloid solutions (e.g., hetastarch) are usually advised in combination with normal saline to support normal blood pressure while minimizing the likelihood of further brain edema (see Table 4.5).

ABSTRACT

Indications for brain surgery include congenital disorders, tumors, and trauma. Neurosurgeons must understand anesthetic considerations relevant to the patient undergoing brain surgery, as well as related concepts of intracranial pressure dynamics. Knowing typical magnetic resonance imaging findings for the various brain disorders encountered by small animal surgeons is vital. Surgeons must also be familiar with approaches to specific brain regions and surgical instrumentation used for brain surgery. Medical management and prognosis of encephalopathies, including antiseizure drug options, chemotherapy, and radiation therapy protocols are of key importance.

KEYWORDS

Brain surgery
intracranial pressure
craniotomy
decompression

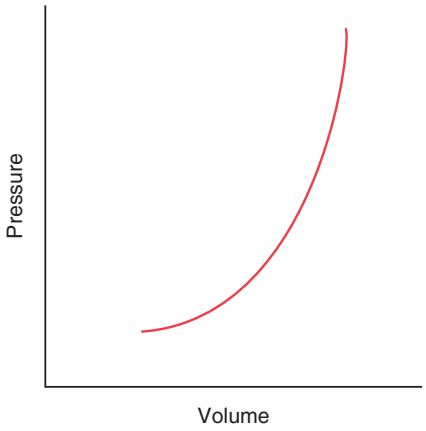


FIG. 39.1 Intracranial pressure versus volume curve.

Depending on the specific disease process, it may be necessary to provide supplemental oxygen to the brain surgery patient before and after surgery. This is often required for victims of severe brain injury. Patients who are conscious and are not obviously deteriorating neurologically should be administered supplemental oxygen via face mask, nasal oxygen catheter, or transtracheal oxygen catheter (see p. 29). Face masks tend to stress dogs and cats and should be used only temporarily, until another form of oxygen (O_2) delivery can be instituted (e.g., nasal O_2). Use of an O_2 cage is generally ineffective for administering supplemental O_2 to severely brain-injured patients because most of these patients require frequent or constant monitoring. Oxygen cages do not allow for concomitant close patient observation (requires opening the cage door) and maintenance of a high-oxygen environment. With nasal and transtracheal O_2 catheters, an inspired oxygen concentration of 40% is provided with flow rates of 100 and 50 mL/kg per minute, respectively. In cases of traumatic brain injury, care must be taken to avoid placing nasal O_2 catheters farther than the level of the medial canthus (to avoid entering the cranial vault through a fracture site). Inadvertent jugular vein compression, which can cause increased ICP, should be avoided while transtracheal O_2 catheters are placed. High flow rates with nasal O_2 catheters may induce sneezing, which can raise ICP. Patients who are losing or have lost consciousness should be intubated and ventilated. In patients with oscillating levels of consciousness or airway obstruction secondary to trauma, a tracheostomy tube may be indicated for assisted ventilation.

IV mannitol (0.5–1.0 g/kg over 10–20 minutes) is the drug of choice for decreasing ICP in brain surgery patients. The most clinically important and immediate (within a few minutes) beneficial effect of mannitol is a decrease in ICP due to decreased blood viscosity and reflex vasoconstriction of brain arterioles. If mannitol is given too rapidly, it causes vasodilation with subsequent increases in cerebral blood volume and ICP and a corresponding decrease in systemic blood pressure. To avoid these blood pressure changes, it is recommended that mannitol be given over 10 to 20 minutes. Over the next 15 to 30 minutes after mannitol administration, fluid is osmotically drawn from extracellular spaces throughout the body, including the brain. Other effects of mannitol include scavenging free radical species and reducing cerebrospinal fluid (CSF) production. Beneficial effects of mannitol last between 2 and 5 hours. Concerns regarding the potential of mannitol to exacerbate preexisting hemorrhage or to cause a reverse osmotic shift are unfounded.

TABLE 39.1 Antiseizure Medications and Oral Dosages for Dogs and Cats

	DOSAGE	
Drug	**Dogs**	**Cats**
Phenobarbital	3–5 mg/kg q12h	2.5 mg/kg q12h
Potassium bromide	35 mg/kg divided, q12h	Not recommended
Gabapentin	10 mg/kg q8h	10 mg/kg q8h
Felbamate	15 mg/kg q8h	Unknown
Zonisamide	5 mg/kg q12h if not on phenobarbital; 8–10 mg/kg q12h if receiving phenobarbital	10 mg/kg q24h
Levetiracetam	20 mg/kg q8h	20 mg/kg q8h
Pregabalin[a]	2–4 mg/kg q12h	1–2 mg/kg q12h
Topiramate[a]	5–10 mg/kg q8–12h	Unknown
Imepitoin	10–30 mg/kg q12h	Unknown

[a]It is recommended to start both pregabalin and topiramate at a low initial dose (e.g., 2 mg/kg q12h) for the first week or two (to avoid sedation).

Antiseizure drugs should be administered to dogs and cats with brain disorders characterized by recurrent seizure activity. A number of alternatives to phenobarbital (PB) and potassium bromide are available for managing seizures in dogs and cats (Table 39.1). Most of these drugs are generic and inexpensive. *Zonisamide* is particularly advantageous to use in dogs with brain tumors. Phenobarbital has the tendency to cause profound sedation in dogs with brain tumors, even at low doses; this effect is sufficiently severe that PB is not recommended in these dogs. Zonisamide does not typically cause sedation and is both effective and inexpensive. Other potentially useful antiseizure drugs for dogs include gabapentin, levetiracetam, felbamate, and pregabalin. *Pregabalin,* the "next generation" of gabapentin, has a longer half-life of elimination than its predecessor and is considered to be more effective. Both pregabalin and gabapentin can cause sedation, although this effect is typically mild. *Levetiracetam* is an extremely useful drug in dogs and cats with brain tumors, particularly when the IV form of the drug is used for short-term management. Levetiracetam seldom has side effects, even at high doses. When side effects occur, sedation and ataxia are most likely. A single bolus injection (20 mg/kg over several minutes) of levetiracetam results in therapeutic plasma levels of the drug for 8 to 12 hours. Levetiracetam does not undergo hepatic metabolism. Oral levetiracetam is a useful drug in both dogs and cats, although a "honeymoon effect" is often seen in dogs with this drug, in which it becomes apparently less effective over time. A potential reason for this phenomenon with levetiracetam may be that the elimination of this drug is accelerated considerably when dogs are concurrently receiving PB. *Felbamate* is an effective and safe antiseizure drug for dogs that does not cause sedation; however, it is expensive, often difficult to acquire, and therefore is used infrequently. *Topiramate* has been shown to be an effective add-on antiseizure drug in one study of refractory canine epilepsy.[1] Reported side effects of topiramate are sedation and ataxia. Topiramate is relatively expensive, and therefore not used frequently by the author. A new antiseizure drug, *imepitoin,* is available in Europe for use in dogs. In one study, imepitoin was

comparable in efficacy with PB in epileptic dogs.[1] Imepitoin does not cause elevations of hepatic enzymes. Reported side effects of imepitoin include sedation, polyuria and polydipsia, increased appetite, and mild, transient hyperactivity; side effects were less likely with imepitoin compared with PB in one clinical trial.[2,3] For cats, PB, levetiracetam, zonisamide, gabapentin, and pregabalin are useful antiseizure drugs. PB is very effective in cats and usually does not produce side effects commonly encountered in dogs, although it can lead to sedation at high plasma concentrations. Oral diazepam and bromide are contraindicated in cats.

In any patient with suspected increased ICP, care should be taken not to compress the jugular veins which will further increase ICP. Additionally, when these patients are recumbent or are being prepared for surgery, the head should be slightly elevated (approximately 30 degrees) to encourage venous drainage from the head and limit venous congestion.

In animals undergoing brain surgery, IV antibiotics (e.g., cefazolin 22 mg/kg) should be administered perioperatively (30 minutes before surgery is begun and every 90–120 minutes thereafter during surgery) and should be discontinued after surgery or within 24 hours. Some neurosurgeons prefer to continue them orally (e.g., cefadroxil 22 mg/kg every 8 hours) for 10 to 14 days postoperatively.

Anesthetic Considerations

Premedication in patients with increased ICP should be avoided. Decreased respirations and hypercapnia may increase ICP and can be lethal. Patients without an increased ICP can be given midazolam or diazepam. Glucocorticoids and anticonvulsants should be continued until surgery.

The induction period needs to be highly controlled in these patients. Barbiturates and propofol are the induction agents of choice (Table 39.2). Alfaxalone is a synthetic neuroactive steroid that acts via gamma-aminobutyric acid type A receptors in the CNS; it can be used for induction and/or maintenance of anesthesia (see Chapter 12). Alfaxalone has been shown to have similar cardiorespiratory effects and quality of anesthesia as propofol. Although the effects of alfaxalone on brain hemodynamics have not been fully investigated in dogs and cats, the predecessor of this drug was shown to have favorable effects on ICP, cerebral metabolic rate (CMR), and cerebral blood flow (CBF).[4,5] A smooth induction and intubation should be performed, with every effort made to avoid blood pressure extremes and prolonged apnea. Hypertension and tachycardia occurring during intubation may have to be treated by administering esmolol or by deepening the anesthetic with additional boluses of propofol, thiopental, or alfaxalone. Hypotension should be quickly treated with vasopressors (e.g., ephedrine or phenylephrine) but not with fluid boluses (see Table 39.2). The airway needs to be secured very carefully because access to the head will be restricted during surgery. Positioning of the animal with its head elevated is beneficial for patients with increased ICP. Take care to avoid occluding the jugular veins when positioning the head to avoid causing an elevation in ICP.

Anesthetic agents influence CBF, cerebral metabolism, CO_2 reactivity, and cerebral blood pressure autoregulation. Barbiturates, propofol, isoflurane, and sevoflurane all decrease cerebral metabolism. Although these anesthetic agents also decrease CBF, it is the decrease in CMR that provides neuroprotection. Barbiturates have been extensively studied in neuroanesthesia and have been used primarily because of their hypnotic effect, decrease in CMR, and anticonvulsant activity. Even though they cause dose-dependent decreases in CBF, barbiturates cause a corresponding decrease in CMR and cerebral oxygen requirements uniformly throughout the brain. Combined with their apparent ability to increase CSF absorption, barbiturates generally cause a decrease in ICP. Propofol acts very similarly, with decreases to CBF, CMR, and ICP. It also has significant anticonvulsant properties. However, systemic vasodilation and subsequent hypotension with propofol administration should be anticipated and treated. Although etomidate decreases ICP, it is avoided in neurosurgery patients because it causes increased seizure activity and thus an increased CMR. Inhalant anesthetics cause a dose-dependent decrease in CMR, as well as an increase in cerebral perfusion. This is especially desirable during periods of hypotension. Isoflurane is the inhalant anesthetic agent of choice because of its ability to increase CSF absorption and to minimally increase ICP (see Table 39.2). Inhalant anesthetics, particularly halothane and desflurane, should be used cautiously in animals with increased ICP.

Particular attention should be paid to $PaCO_2$ in anesthetized brain surgery patients because hypercapnia can lead to severe increases in ICP and decreased CPP. Most anesthetic drugs used clinically have the potential to cause hypoventilation and resultant hypercapnia. Arterial blood gas measurement is the best way to monitor $PaCO_2$ levels. End-tidal CO_2 ($EtCO_2$) measurement is a useful monitoring tool but tends to underestimate true $PaCO_2$ levels. In patients that have normal pulmonary function, $EtCO_2$ is approximately 5 mm Hg greater than $PaCO_2$. In younger animals, the number is lower, and in animals younger than 1 year, $EtCO_2$ may be equal to $PaCO_2$. These gradients cannot be unilaterally assumed with all patients because of alterations in pulmonary function, especially in anesthetized patients, in which atelectasis and ventilation/perfusion mismatching occur. Nevertheless, $EtCO_2$ can serve as a guideline and, when used with arterial blood gases during neurosurgery, is an important part of monitoring. Venous CO_2 concentration ($PvCO_2$) is also helpful and is usually less than 5 mm Hg greater than $PaCO_2$. However, in patients with perfusion deficits, peripheral $PvCO_2$ levels can be significantly higher than arterial values and should be interpreted cautiously. Historically, it has been recommended to keep $PaCO_2$ levels in the range of 25 to 35 mm Hg to prevent excessive brain vasodilation. Recent evidence suggests that $PaCO_2$ less than 30 mm Hg may lead to excessive vasoconstriction with subsequent impairment of CPP. Excessive hyperventilation may be deleterious to patients whose ICP elevation is not caused by hypercarbia-induced dilation of brain vasculature. Mild hyperventilation to keep $PaCO_2$ between 30 and 35 mm Hg is currently used in human neurosurgical patients. Indiscriminate use of hyperventilation to decrease ICP should be avoided, especially in trauma patients. However, it may be warranted for short periods in emergency cases in which the brain stem is herniating, until more definitive therapy can be initiated.

In general, anesthetic agents considered preferable for use in brain surgery patients include benzodiazepines (e.g., diazepam, midazolam), barbiturates (e.g., pentobarbital), propofol, opioids, isoflurane, and sevoflurane (see Table 39.2). As mentioned previously, it is believed that alfaxalone also has favorable effects on brain hemodynamics, although this is less well-established than it is with other drugs. Opioids have little to no effect on ICP, and pentobarbital, propofol, and benzodiazepines decrease ICP with some neuroprotective properties. The potential adverse effects of opioids on ICP are minimal to nonexistent if appropriate doses are used. The concern is depression and inadequate respirations

TABLE 39.2 Anesthetic Considerations and Drugs for Dogs and Cats Undergoing Brain Surgery

Preoperative Considerations

Associated conditions	• May be young with other congenital defects • If traumatic brain injury, may have evidence of other trauma • If older patient, may have other comorbidities
Bloodwork	HCT Electrolytes, especially sodium Serum creatinine ALT TP Blood glucose Urinalysis Blood gas, if available
Physical examination	Varies according to cause May be depressed and/or painful
Other diagnostics	Blood pressure ECG Radiographs (thoracic ± abdominal) CT or MRI

Premedications	• Oxygen with flow-by or face mask
	• Avoid sedatives in depressed patients or when increased ICP is known or suspected
	• Prednisolone (0.25–1 mg/kg PO, IV) when indicated
	• Administer GI protectant of choice
	• In patients that have minimal depression, give:
	  • Midazolam (0.2 mg/kg IV, IM), *or*
	  • Diazepam (0.2 mg/kg IV)
	• Before induction, avoid all respiratory depressants, including but not limited to opioids. Avoid acepromazine, xylazine, medetomidine, and dexmedetomidine in depressed, hypotensive, or elderly patients.

Intraoperative Considerations

Induction	Preoxygenate for 3 minutes with face mask or flow-by oxygen then give:
	  • Thiopental (if available, see p. 133; 6–10 mg/kg IV bolus), *or*
	  • Propofol (2–8 mg/kg, IV bolus)
	  • Alfaxalone (2–5 mg/kg, IV bolus)

Maintenance	• Isoflurane preferred, *plus*
	  • Fentanyl (2–10 µg/kg IV PRN in dogs; 14 µg/kg in cats) for short-term pain relief, *plus* PRN
	  • Fentanyl CRI (1–5 µg/kg IV loading dose, then 2–30 µg/kg/h IV), *or*
	  • Hydromorphone[a] (0.05–0.2 mg/kg IV PRN in dogs; 0.05–0.1 mg/kg IV PRN in cats), *or*
	  • Oxymorphone (0.05–0.2 mg/kg IV), *or*
	  • Morphine[b] (0.1–1 mg/kg IV PRN in dogs; 0.05–0.2 mg/kg IV PRN in cats), *or*
	  • Buprenorphine[c] (0.005–0.02 mg/kg IV PRN)
	• If hypotensive (to keep MAP 60–80 mm Hg), give phenylephrine, ephedrine, norepinephrine, or dopamine (see Box 19.6)
	• Position patient with head elevated if possible but avoid jugular vein occlusion
	• Mannitol (0.5–1 g/kg IV over 10–20 min) if needed for cerebral edema
	• Hypertonic saline (4 mL/kg IV) if needed for brain edema
	• Ventilation parameters:
	  • Controlled or assisted ventilation is necessary
	  • SpO_2 >95%
	  • $EtCO_2$ 35–40 mm Hg
	  • $PaCO_2$ 30–35 mm Hg
	  • Tidal volumes 7–10 mL/kg
	  • Respiratory rates 10–20
	  • Peak airway pressures <20 mm Hg
	  • Avoid prolonged inspiratory times
	  • Avoid positive end-expiratory pressure

Fluid needs	• 7–10 mL/kg/h to replace evaporative losses plus 3 × EBL. • Consider colloids for EBL replacement in 1:1 ratio (see Table 4.5)
Monitoring	• BP • ECG • Respiratory rate • SpO_2 • $EtCO_2$ • Temperature • Arterial line • U/O (urinary catheter is needed if diuretics are used) • Repeat sodium levels if mannitol is given

Continued

TABLE 39.2 Anesthetic Considerations and Drugs for Dogs and Cats Undergoing Brain Surgery—cont'd

Postoperative Considerations

Analgesia	• Fentanyl CRI (1–10 µg/kg IV loading dose, then 2–20 µg/kg/h IV), *or* • Hydromorphone CRI (0.025–0.1 mg/kg/h IV in dogs), *or* • Hydromorphone[a] (0.05–0.2 mg/kg IV, IM q3–4h in dogs; 0.05–0.1 mg/kg IV q3–4h in cats), *or* • Oxymorphone (0.05–0.2 mg/kg IV, IM q3–4 h), *or* • Morphine[b] (0.1–1 mg/kg IV or 0.1–2 mg/kg IM q1–4h in dogs; 0.05–0.2 mg/kg IV or 0.1–0.5 mg/kg IM q1–4h in cats), *or* • Buprenorphine[c] (0.005–0.02 mg/kg IV, IM q4–8h or 0.01–0.02 mg/kg OTM q6–12h in cats)
Monitoring	SpO2 Blood pressure ECG HR Respiratory rate Temperature U/O
Bloodwork	HCT TP Electrolytes, especially sodium, if mannitol was given Blood gas Blood glucose
Estimated pain score	Mild to moderate

[a]Monitor for hyperthermia in cats.
[b]Give slowly to prevent histamine release.
[c]Buprenorphine is a better analgesic than morphine in cats.
ALT, Alanine aminotransferase; *BP,* blood pressure; *CRI,* constant-rate infusion; *CT,* computed tomography; *EBL,* estimated blood loss; *ECG,* electrocardiogram; *$EtCO_2$,* end-tidal CO_2; *GI,* gastrointestinal; *HCT,* hematocrit; *HR,* heart rate; *ICP,* intracranial pressure; *IM,* intramuscular; *IV,* intravenous; *MAP,* mean arterial pressure; *MRI,* magnetic resonance imaging; *OTM,* oral transmucosal; *$PaCO_2$,* partial pressure of carbon dioxide; *PO,* orally; *PRN,* as needed; *SpO_2,* hemoglobin saturation with oxygen; *TP,* total protein; *U/O,* urine output.

causing elevations in $PaCO_2$. Therefore it is recommended that opioids not be used in the preoperative period but rather during surgery, when ventilation is controlled, and during the postoperative period. Poorly controlled pain is much more likely to increase ICP than is judicious use of opioids postoperatively. Additionally, continuous-rate infusions of opiates (e.g., fentanyl, morphine) begun during surgery and continued into the postoperative period are less likely to lead to respiratory depression with a subsequent ICP increase due to hypercapnia (see p. 132).

Because of known negative effects on brain autoregulatory mechanisms and tendencies to increase ICP, anesthetic drugs to be avoided include ketamine, halothane, and desflurane. Ketamine is a controversial drug that was initially considered contraindicated in patients with increased ICP. Traditionally it was thought to always increase CBF; however, it has been shown NOT to increase CBF or ICP in mechanically ventilated animals. In fact, mechanically ventilated, traumatic brain injury human patients have a decreased ICP. Ketamine may also have a neuroprotective effect because of the antagonism of *N*-methyl-D-aspartate receptors, but this is unproven. Nevertheless, giving ketamine to already intubated and ventilated patients is not the same as inducing with ketamine. There are better choices that do not carry the risk of marked hypertension at induction, hence ketamine is not recommended.

The alpha-2 agonists dexmedetomidine, medetomidine, and xylazine have some neuroprotective qualities. Both dexmedetomidine and medetomidine decrease ICP in patients already anesthetized with an inhalant anesthetic. Unfortunately, their variable effects on blood pressure make them less appropriate as induction drugs. However, if used in low doses in a balanced anesthesia protocol, they may reduce the hypertension followed by hypotension seen in these patients (see Table 39.2).

Traditionally, acepromazine has been thought to potentiate seizure activity in patients predisposed to seizures. Clinical evidence contradicts this historical dogma. Very low doses of acepromazine (0.01–0.02 mg/kg IV) are often helpful in relieving what appears to be postoperative dementia in some brain tumors and brain trauma patients. As with other drugs, acepromazine at higher doses can cause hypotension, which can have deleterious effects on ICP and CPP. Furthermore, patients with intracranial masses are often older patients, and acepromazine may have long-lasting effects.

STANDARD SURGICAL APPROACHES TO THE BRAIN

Important vascular structures to avoid during brain surgery are the dorsal sagittal sinus and the transverse sinuses (Fig. 39.2). Laceration of these structures can cause life-threatening hemorrhage. Ligation or obstruction of the dorsal sagittal sinus (particularly the caudal two-thirds of the sinus), the confluens sinuum (the midline juncture of the paired transverse sinuses), or both transverse sinuses will probably cause fatal brain swelling. During the suboccipital approach, it is common to experience hemorrhage from occipital emissary veins at the ventrolateral limits of the supraoccipital bone during periosteal muscle elevation; this hemorrhage is controlled by pushing bone wax into the mastoid foramen through which this vessel traverses.

For all standard approaches, the author prefers a midline incision. Unless brain exposure is very large (e.g., removal of the top portion of the calvarium) or the craniotomy procedure is likely to lead to an obviously abnormal cosmetic appearance postoperatively (e.g., removal of the zygomatic process of the frontal bone), the craniotomy defect is not repaired. If repair of the skull defect is considered necessary, titanium mesh and polymethylmethacrylate (PMMA) can be used (Fig. 39.3). The PMMA is placed on either side of the mesh; the mesh

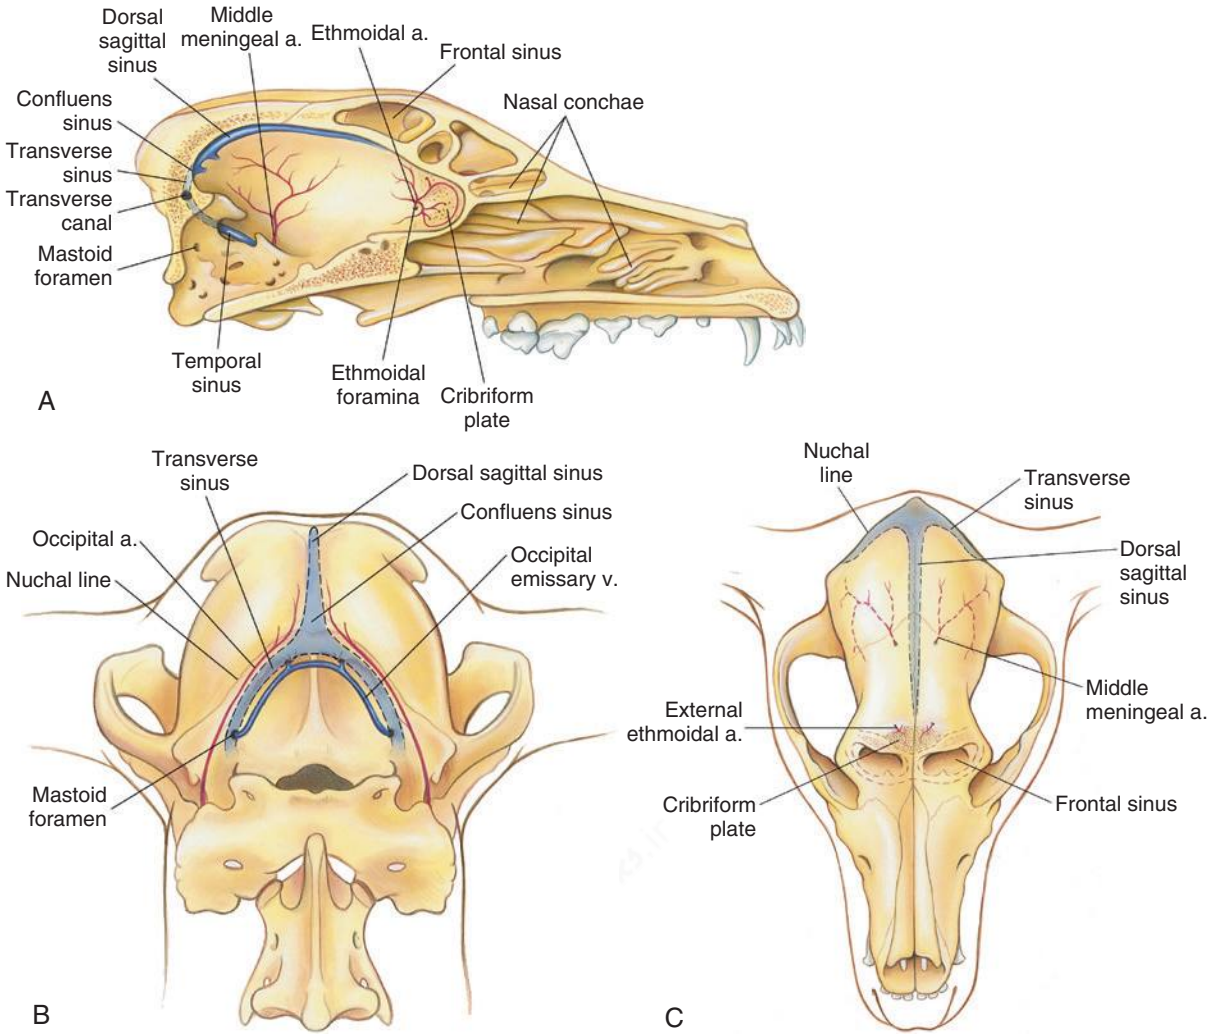

FIG. 39.2 Schematic illustration of the canine skull, showing important surgical landmarks and vascular structures. (A) Mid-sagittal view. (B) Caudal view. (C) Dorsal view.

keeps the PMMA from sagging into the craniotomy site during hardening. Titanium rather than steel is used so that repeat MRI is possible if necessary. Postoperative CSF leakage is a clinical problem encountered in human brain surgery; however, this phenomenon does not occur in dogs and cats following craniotomy. Replacing resected dura/arachnoid with autologous or synthetic dural substitute is generally not necessary in dogs and cats; however, the author repairs dural defects if the craniotomy necessitates invasion of the frontal sinus area. A layer of Gelfoam can be placed over the exposed brain before the time of closure.

Once the dura/arachnoid is opened and the brain is exposed, it is important for the surgeon to be efficient in his/her use of time. Although surgery is "not a race," prolonged brain tissue exposure appears to be associated with increased postoperative morbidity, even when appropriate measures are taken to keep the brain moist during surgery (e.g., moistened lint-free cottonoid sponges placed on the brain surface).

Rostrotentorial (Lateral) Craniotomy

Shave the skin and aseptically prepare the area from the level of the medial canthi rostrally to the cranial aspect of the second cervical vertebra caudally; the lateral limits of the prepared region are the zygomatic arches. Shave and aseptically prepare any aspect of the ears that may be in the surgical area. Make a midline incision from approximately the level of the lateral canthi to several centimeters past the external occipital protuberance. Sharply incise the cutaneous coli muscles and transect the cervicoscutularis muscle near midline, leaving approximately a centimeter for reattachment during closing. Sharply incise the temporalis fascia with a No. 11 blade, leaving at least several millimeters attached to the skull for reattachment purposes. Reflect the temporalis musculature ventrally by elevating it off the side of the skull with Freer periosteal elevators (cats and small dogs) or Army-Navy osteotomes (large dogs). Create an oval outline of the intended defect with a high-speed air drill. Deepen the edges of this outline until a thin layer of periosteum is left. The ventral aspect of the defect does not have to be drilled full thickness. *Once the dorsal and lateral aspects of the craniotomy defect outline are completely drilled, use a periosteal elevator to lever the bone flap off the skull after positioning the elevator in the dorsal aspect of the defect (Fig. 39.4). Once the bone flap is removed, further enlarge the craniotomy defect using rongeurs. After removal of the bone flap, use bipolar cautery to stop hemorrhage from bleeding meningeal vessels.*

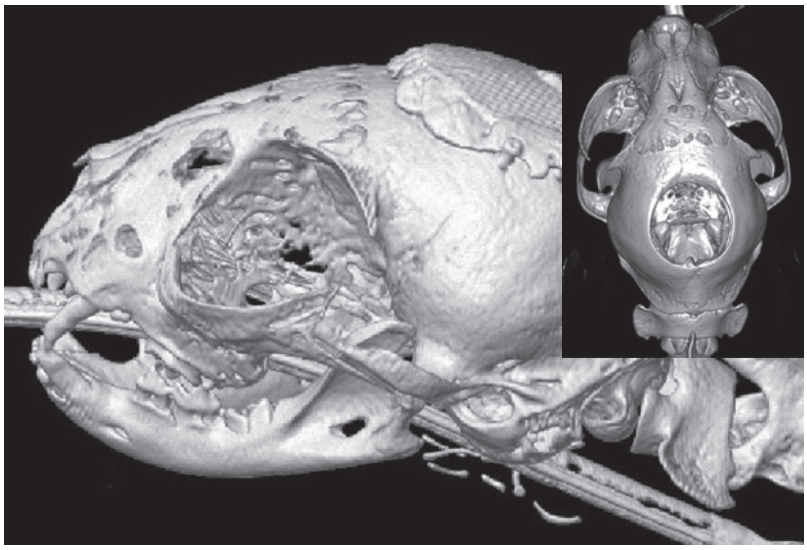

FIG. 39.3 Postoperative three-dimensional computed tomography–reconstructed image of a cat with a meningoencephalocele that had a skull defect *(inset)* repaired with a titanium/polymethylmethacrylate plate. (From Dewey CW, Brewer DM, Cautela MA, et al. Surgical treatment of a meningoencephalocele in a cat. *Vet Surg.* 2011;40:473.)

Transfrontal Craniotomy

The most common reason for performing a transfrontal craniotomy is to remove canine meningiomas in the olfactory bulb region of the brain. Several variations of this approach provide excellent access to the olfactory bulb area and the rostral frontal lobe (prefrontal area) of the cerebrum—areas that are difficult or impossible to access via a standard rostrotentorial craniotomy. As with other approaches, this transfrontal craniotomy approach can be expanded caudally, on either side of the skull, should increased exposure or further brain decompression be required.

Shave the skin and aseptically prepare it from the level of the infraorbital foramina rostrally to the level of the caudal aspect of the zygomatic arches dorsally. Extend the lateral limits of the prepared skin area to the level of the zygomatic arches and include the skin around the eye. Make a midline incision rostrally from the level of the medial canthi to the level of the bregma. Using a combination of sharp dissection and Freer elevators, separate the underlying subcutaneous tissues and frontalis musculature from the underlying bone. Remove the outer bone plate of the frontal sinus to expose the frontal sinus, the ethmoturbinates, and the internal table of the frontal bone.

This bone can be removed in a variety of sizes and shapes with the use of a high-speed air drill or an oscillating saw blade. A triangular shape is often chosen for a unilateral approach, or a diamond pattern for a bilateral approach (Fig. 39.5). Because of the limited exposure (most olfactory meningiomas occupy the majority of the olfactory bulb region bilaterally) provided by the unilateral approach, the bilateral approach is typically performed. *If the bone plate is to be replaced, use the saw blade or a small drill bit when removing the bone.*

Suboccipital Craniotomy (Foramen Magnum Decompression)

The most common indication for a suboccipital craniotomy in dogs is to relieve compression at the craniocervical junction in cases of Chiari-like malformation (CLM). In this scenario, the craniotomy is combined with a dorsal laminectomy of the atlas (C1) and is referred to as a *foramen magnum decompression* (FMD). For other purposes (e.g., brain tumor removal), the suboccipital craniotomy is typically performed without including the C1 dorsal laminectomy. If more exposure is required (e.g., brain tumor removal from the caudal fossa), the suboccipital craniotomy can be extended rostrally on one side by sacrificing one transverse sinus. *For any version of this procedure, place the dog in sternal recumbency with the neck ventroflexed. Shave and aseptically prepare the dorsal aspect of the head and neck from the level of the bregma to the level of the third or fourth cervical vertebra, with a width approximately equal to the width of the atlas. Make a dorsal midline incision extending from approximately 1 cm rostral to the external occipital protuberance cranially to the middle of the second cervical vertebra caudally. Separate the superficial dorsal cervical musculature (Fig. 39.6A) at the median raphe, exposing the underlying biventer cervicis muscles. Separate the paired biventer cervicis muscles on midline, exposing the rectus capitis dorsalis muscles (Fig. 39.6B). Remove the caudal aspects of the rectus capitis dorsalis muscles from the cranial half of C2 using sharp dissection and periosteal elevation, and split these muscles on the midline. Sharply incise the cranial aspects of the rectus capitis dorsalis muscles from the nuchal crest, exposing the caudal portion of the occiput and the arch of the atlas. Control hemorrhage with bipolar electrocautery. Use a high-speed air drill with a 3- to 4-mm diameter round drill bit and Lempert rongeurs to remove a portion of the occiput and the dorsal aspect of the first cervical vertebra (Fig. 39.6C–D).* Approximately 75% of the length of the dorsal arch of C1 is routinely removed. *In cases in which there appears to be dorsal constriction at C1–C2 (see Chapter 40), remove the entire arch of C1 as well as part of the dorsal lamina of C2.*

HEALING OF THE BRAIN

Damaged brain tissue heals via glial proliferation (glial "scar"). A connective tissue covering ("neo dura") forms over incised or

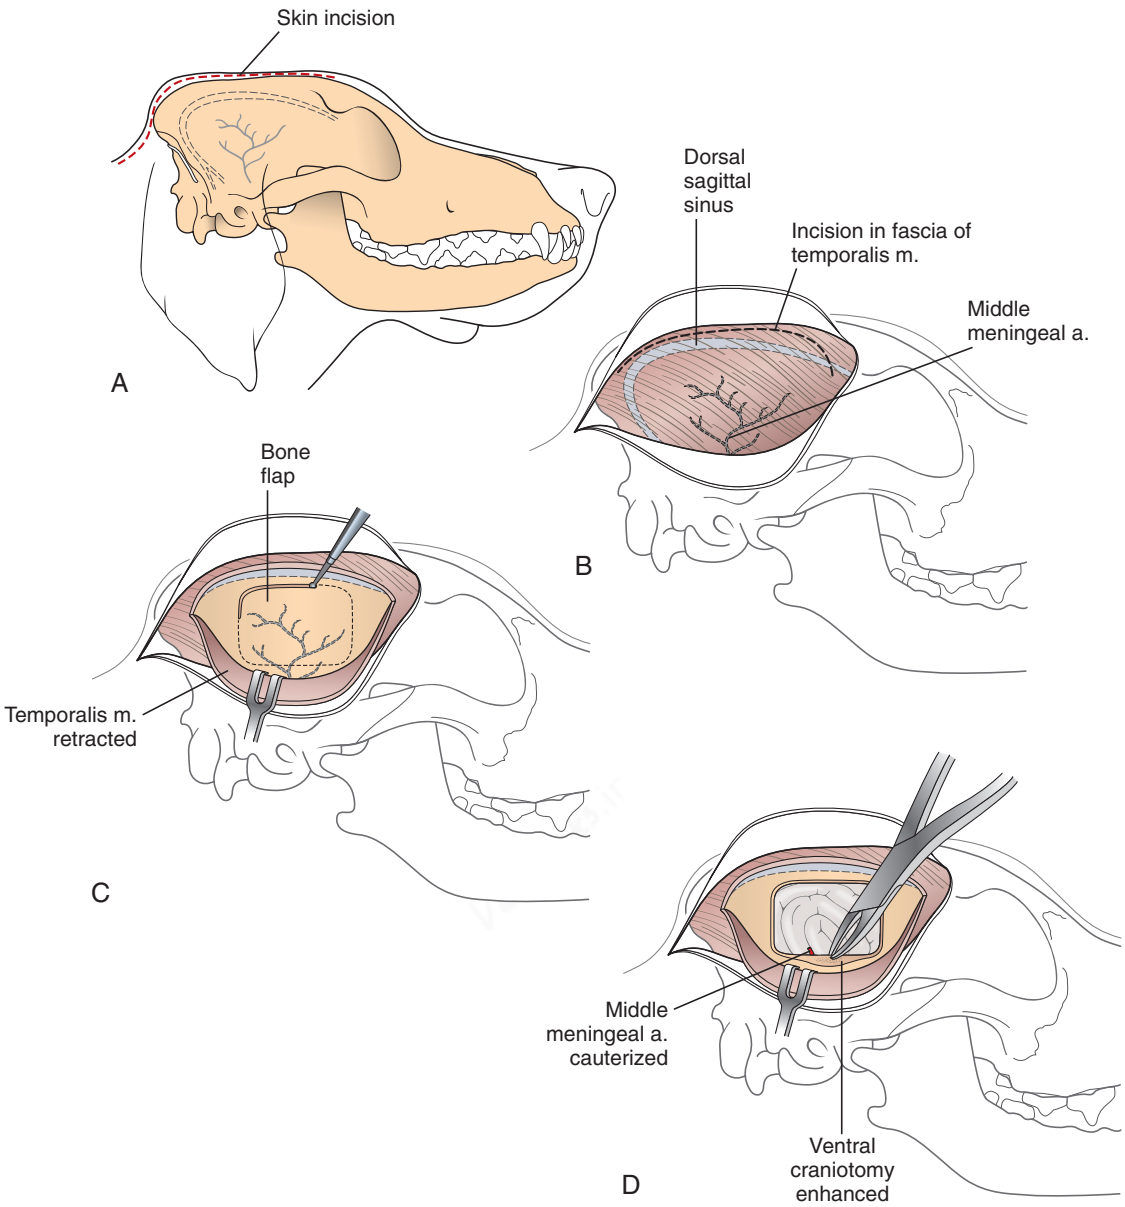

FIG. 39.4 Using a high-speed air drill, create an oval outline for the intended craniotomy defect as shown. The dorsal and lateral aspects of this defect need to be drilled completely through. If a groove is present in the ventral aspect, it will break off when the bone flap is levered off the skull.

resected dura/arachnoid within 2 months of surgery. Surrounding musculature will adhere to the outer surface of this covering, but CSF typically separates the brain from the inner surface of this membrane. If a bone flap is replaced or a synthetic covering (e.g., PMMA, titanium mesh/PMMA) is applied to the craniotomy defect, the neo dura may be adherent to the bone or synthetic flap if the patient undergoes reoperation for tumor recurrence.

SUTURE MATERIALS AND SPECIAL INSTRUMENTS

Instruments essential for performing brain surgery include a high-speed air drill, rongeurs of several styles (e.g., Lempert, Kerrison, Ruskin; see Figs. 7.17 and 7.18), microsurgical instrumentation (e.g., several sizes of probes, strabismus and tenotomy scissors, nontoothed Bishop-Harmon forceps, lens loops [see Fig. 16.3]), and several sizes of Frazier suction tips. Small needle holders (e.g., Castroviejo) and 5-0 to 6-0 suture material (polypropylene or polydioxanone) are needed for meningeal suturing. Monopolar cautery is needed for hemorrhage during the surgical approach. Bipolar cautery is required for dealing with meningeal, tumor, and brain parenchymal hemorrhage. Gelfoam and Surgicel are also helpful in controlling meningeal and parenchymal hemorrhage. Bone wax is used to control hemorrhage from cancellous bone and transverse

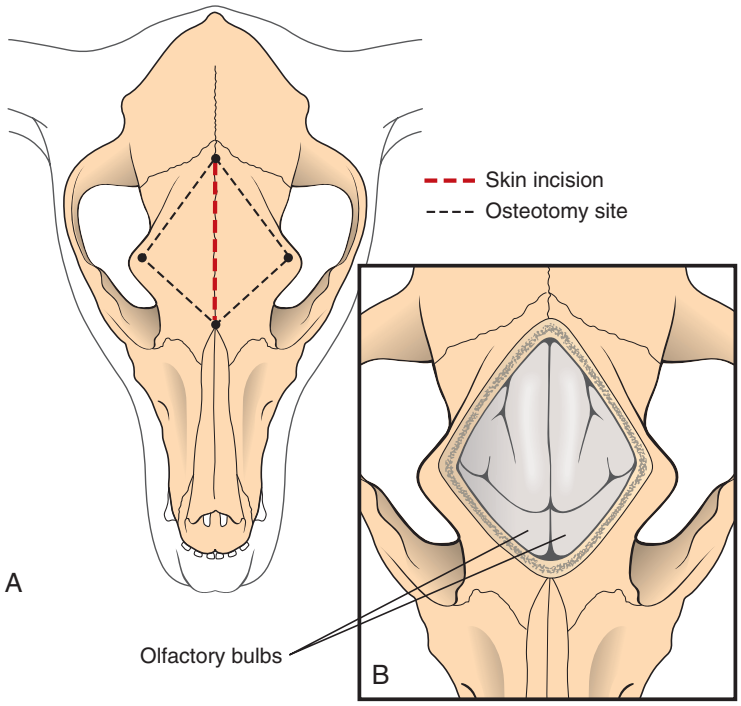

FIG. 39.5 For modified bilateral transfrontal craniotomy: (A) make a midline incision from the caudal edge of the nasal bones at the level of the medial canthus of the eye caudally to the caudal extent of the frontal sinus. (B) Remove a diamond-shaped bone flap using an oscillating bone saw. Then remove the internal table of the frontal bone and a portion of the ethmoturbinates using a rongeur.

sinuses (if transected). Lint-free cottonoid sponges are used to keep the brain moist while it is exposed. Magnification is often useful and is typically provided by optical telescopes. An additional light source (e.g., headlamp) may be needed for some procedures. A Cavitron ultrasonic aspirator (CUSA) is useful for resecting infiltrative masses or working near blood vessels; the high cost of this equipment may limit its use, however. Intraoperative ultrasound is useful both in locating intraaxial lesions and in judging the completeness of their removal before the time of closure.

POSTOPERATIVE CARE AND ASSESSMENT

All postoperative craniotomy patients should be recovered in an intensive care unit and monitored for 3 to 5 days postoperatively. The cage should be padded (e.g., with bubble wrap) to avoid injury to the surgical site. Because postoperative brain surgery patients may have subtle pharyngeal dysfunction, nothing is given per os for the first 24 hours. After this time, small "meatballs" of canned food are offered several times a day, in addition to water. For patients on oral prednisolone therapy, this therapy is gradually tapered over 5 to 7 days. Antibiotics are continued according to the specifics of the disease process and clinician preference. Anticonvulsant drugs and analgesics (see Table 39.1 and Chapter 13) should be administered as needed. Serial packed cell volume (PCV) measurements should be made for the initial 24 hours after surgery and blood transfused as necessary, especially in cats. Oxygenation and ventilation status should be assessed via blood gas analysis, depending on the specific case. Supplemental oxygen should be provided if necessary.

For patients that are unable or unwilling to voluntarily ambulate, frequent turning (e.g., every 4 hours) is essential to avoid pulmonary atelectasis and subsequent pneumonia. The patient's neurologic status should be assessed several times per day, and any deterioration addressed medically (e.g., mannitol) and/or surgically (reimaging and reoperation). Suspected pneumonia (typically older, large dogs following brain tumor removal) should be treated aggressively (e.g., nebulization/coupage, broad-spectrum IV antibiotics) in a timely manner. Following hospital discharge, recheck examinations focus on the rate of neurologic recovery and on wound healing.

COMPLICATIONS

Potential intraoperative and immediate postoperative complications of brain surgery include brain swelling, hemorrhage, and cardiopulmonary dysfunction (e.g., brainstem surgery). Postoperative complications include anemia (primarily cats following meningioma removal), pneumonia (mainly large, older dogs after brain tumor removal), seizures, wound infection, and tumor recurrence.

SPECIAL AGE CONSIDERATIONS

In older dogs and cats, the dura is often adhered to the endosteum of the calvaria, so it may be stuck to the bone flap as the flap is removed. Sometimes the tumor (meningioma) is also attached to the bone flap/dura in these patients. Older dogs, especially of larger breeds, are at risk for postoperative pneumonia following brain tumor removal.

SPECIFIC DISEASES

CONGENITAL HYDROCEPHALUS

DEFINITION

Congenital hydrocephalus is an abnormal accumulation of CSF within the ventricular system (primarily lateral ventricles) of the brain that can lead to clinical signs of encephalopathy.

GENERAL CONSIDERATIONS AND CLINICALLY RELEVANT PATHOPHYSIOLOGY

The pathophysiology of CNS damage associated with hydrocephalus is complex and involves destruction of the ependymal lining of the ventricles, white matter damage by interstitial fluid accumulation, and eventual neuronal injury in the cerebral cortex.

Conventional theories regarding the pathophysiology of hydrocephalus contend that ventriculomegaly results from obstruction of CSF flow within the ventricular system (e.g., mesencephalic aqueduct stenosis) and/or insufficient absorption of CSF into the venous system at the arachnoid villi level. These theories are based on the "bulk flow" concept of CSF, in which most CSF is presumed to be absorbed by the arachnoid villi. A more recently proposed theory, called the *hydrodynamic theory*, maintains that hydrocephalus develops as the result of abnormal (reduced) intracranial compliance and the resultant effect of this compliance defect on brain capillaries. In the normal animal, individual brain capillaries remain open during the entire cardiac

cycle (systole and diastole). This is important because much of CSF absorption actually occurs at the capillary level, rather than at the arachnoid villi. Hydrocephalic patients are believed to have poor intracranial compliance as an underlying disorder that leads to hydrocephalus. The increased capillary pulse pressure caused by decreased compliance leads to a pulsatile transmantle pressure gradient directed from the cerebral tissue toward the lateral ventricles. These abnormal capillary pulsations can occur within normal mean ICP limits. Rebound pressure from the recurring gradient, as well as hyperdynamic CSF flow in the mesencephalic aqueduct, leads to ventricular enlargement over time (increased intraventricular pressure). The end result is that hydrocephalus may develop within the confines of normal ICP (i.e., normal pressure hydrocephalus). Hydrocephalus, especially if progressive, can cause neurologic dysfunction from compression and stretching of brain parenchyma, as well as from brain ischemia and interstitial edema.

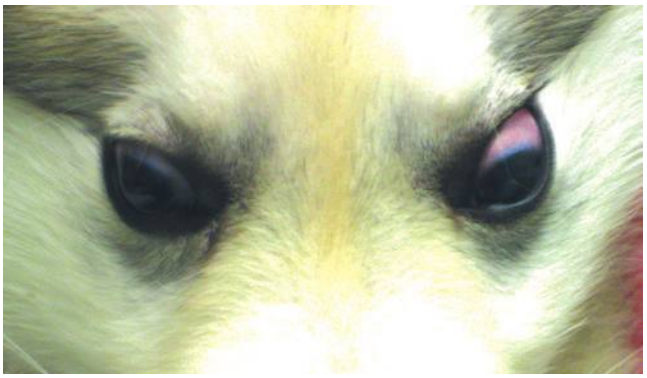

FIG. 39.7 Puppy with congenital hydrocephalus exhibiting bilateral ventrolateral strabismus.

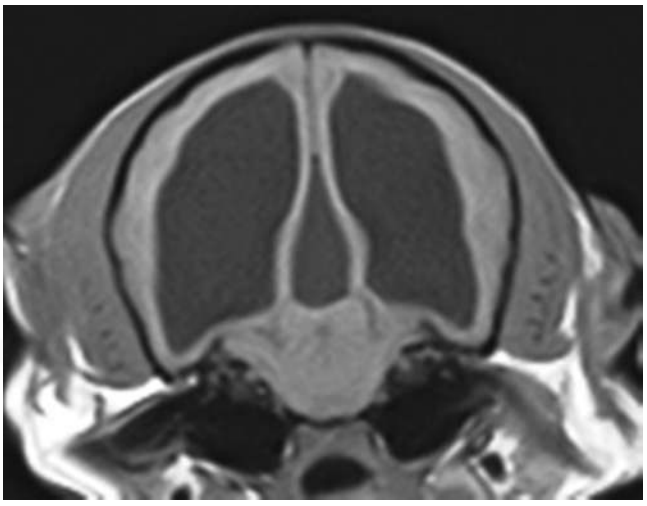

FIG. 39.8 T2-weighted axial brain image of a dog with congenital hydrocephalus.

DIAGNOSIS

Clinical Presentation

Signalment

Congenital hydrocephalus is most commonly reported in dogs, especially small breeds (e.g., Chihuahua, Yorkshire terrier, Maltese, Boston terrier, English bulldog, toy/miniature poodle, Lhasa apso, Pomeranian, Pekingese).

History

Affected animals typically have a history of clinical signs of neurologic dysfunction, including obtunded mentation (see p. 1323), behavior abnormalities, circling, pacing, restlessness, and seizure activity. Seizures are much less commonly associated with congenital hydrocephalus than are behavioral abnormalities and abnormal mentation. Some hydrocephalic patients may also exhibit vestibular and/or cerebellar dysfunction. Many animals, especially of predisposed breeds (see earlier), may have "hydrocephalus" based on lateral ventricular enlargement appreciated on advanced imaging, yet have no discernible neurologic dysfunction. It is important to distinguish ventriculomegaly, which is considered a variant of normal for a number of breeds, from clinical hydrocephalus (see Diagnostic Imaging).

Physical Examination Findings

Common physical characteristics of hydrocephalic patients include a large, dome-shaped head, open fontanelles or larger calvarial defects, and bilateral ventrolateral strabismus (Fig. 39.7). The strabismus may be due to orbital skull malformation, rather than to vestibular dysfunction, and has been referred to as the *setting sun sign*. It is important to realize that small-breed dogs often have open fontanelles with no attendant clinical signs of neurologic dysfunction. Concurrent congenital abnormalities of the brain (e.g., IAC, Dandy-Walker syndrome, CLM) occasionally occur in hydrocephalic dogs, accounting for cerebellovestibular dysfunction.

Diagnostic Imaging

Diagnosis of congenital hydrocephalus is based on a combination of characteristic clinical features, demonstration of ventriculomegaly, and the absence of other causes of encephalopathy. Ultrasonography (through open fontanelles or calvarial defects) and advanced imaging techniques (i.e., computed tomography [CT] and MRI) (Fig. 39.8) have supplanted more invasive methods of documenting ventriculomegaly (e.g., contrast ventriculography). A vast majority of congenital hydrocephalus cases involve primarily dilation of the lateral ventricles (internal hydrocephalus). Occasionally, the bulk of CSF accumulation is within the subarachnoid space (external hydrocephalus), with the brain displaced axially (Fig. 39.9). MRI is the preferred imaging modality for the diagnosis of hydrocephalus. In addition to providing superior anatomic detail, there are certain MRI characteristics that can help differentiate clinically relevant hydrocephalus from asymptomatic ventriculomegaly. In a recent retrospective study, certain MRI characteristics were helpful in distinguishing clinically relevant internal hydrocephalus from asymptomatic ventriculomegaly.[6] Electroencephalography has been used historically to assist in the diagnosis of congenital hydrocephalus; affected patients typically exhibit slow-frequency, high-voltage activity. However, these electroencephalography findings are relatively nonspecific and seldom contribute to the diagnosis of congenital hydrocephalus.

Laboratory Findings

Results of complete blood count, serum biochemical profile analysis, and CSF analysis are typically normal in affected animals.

FIG. 39.9 T2-weighted axial brain image of a cat with external hydrocephalus.

DIFFERENTIAL DIAGNOSIS

Diseases that may lead to clinical signs of encephalopathy in young dogs and cats should be considered as differentials. Additionally, the possibility of secondary hydrocephalus (i.e., obstructive hydrocephalus due to a brain tumor) needs to be ruled out. Degenerative diseases (e.g., lysosomal storage diseases), anomalous conditions (e.g., IAC), metabolic problems (e.g., hepatic encephalopathy, mitochondrial encephalopathy/organic aciduria), inflammatory/infectious disease (e.g., granulomatous meningoencephalomyelitis [GME], necrotizing encephalitis, canine distemper virus infection), and toxin exposure should be considered in these patients. In most cases, signalment and physical characteristics (e.g., dome-shaped head, bilateral ventrolateral strabismus) are fairly specific for a diagnosis of congenital hydrocephalus.

MEDICAL MANAGEMENT

Medical therapy may be effective in some patients, whereas others require surgical shunting procedures for long-term control of clinical signs. Medical treatment of congenital hydrocephalus is directed at reduction of CSF production. In the author's opinion, medical therapy for patients with obvious neurologic signs attributable to hydrocephalus is usually ineffective, especially in the long term. Oral prednisolone, at an initial dosage of 0.25 to 0.5 mg/kg every 12 hours, may decrease CSF production (Table 39.3). Prednisolone should be reduced over several weeks to the lowest possible dosage required to control clinical signs. Furosemide, a loop diuretic, decreases CSF production via inhibition of the sodium/potassium cotransport system (see Table 39.3). The diuretic acetazolamide is a carbonic anhydrase inhibitor (carbonic anhydrase is a necessary enzyme for CSF production) that is typically dosed at 10 mg/kg body weight, orally every 6 to 8 hours. Omeprazole, a proton pump inhibitor, has been shown to decrease CSF production in dogs, although the clinical effectiveness of this drug has not been documented. For all of these drugs, it is recommended that the dose be tapered to the lowest amount needed to control clinical signs of disease to avoid serious side effects. Anticonvulsant drugs should be administered if the patient seizures. As mentioned, medical therapy for congenital hydrocephalus may provide some level of disease palliation in mild cases but often fails in the long term. When treatment decisions are made, the potential side effects of long-term corticosteroid and/or diuretic therapy should be considered, along with the questionable efficacy of medical therapy for congenital hydrocephalus. Electrolyte depletion (especially potassium) and dehydration are concerns when diuretics are used for prolonged periods, particularly when combined with glucocorticoids.

TABLE 39.3 Drugs for Treatment of Congenital Hydrocephalus

Drug	Dosage
Prednisolone	0.25–0.5 mg/kg PO q12h
Furosemide	0.5–4.0 mg/kg PO q12–24h
Acetazolamide	10 mg/kg PO q6–8h
Omeprazole	10 mg q24h (dogs <20 kg); 20 mg q24h (dogs >20 kg) PO

PO, Orally.

SURGICAL TREATMENT (Videos 39.1 and 39.2)

The goal of surgical treatment of hydrocephalus is to continually divert excessive CSF from the ventricles of the brain to the peritoneal cavity. A number of shunts are available, all of which have the same basic design: a rostral end for placement into the lateral ventricle, a one-way valve, and a distal end for placement into the peritoneal cavity (Fig. 39.10).

Preoperative Management

See p. 1338 for preoperative management of the brain surgery patient.

Anesthesia

See p. 1340 for anesthetic management of the brain surgery patient.

Surgical Anatomy

See Chapter 38 and p. 1342 for surgical anatomy of the skull and brain. Patients with congenital hydrocephalus may have sections of skull missing, in addition to the classic midline open fontanelles. Familiarity with the orientation of the abdominal musculature in the flank area is essential for performance of a grid approach to the peritoneal cavity. At the level of the flank incision, the external abdominal oblique muscle is directed caudoventrally, the internal abdominal oblique muscle is oriented in a caudodorsal direction, and the transversus abdominis runs in a dorsoventral direction, essentially parallel to the last rib.

Positioning

The front end of the patient is placed in sternal recumbency, with the head in a neutral angle. The pelvic limbs are directed laterally, toward the surgeon, so that the flank is oriented in a

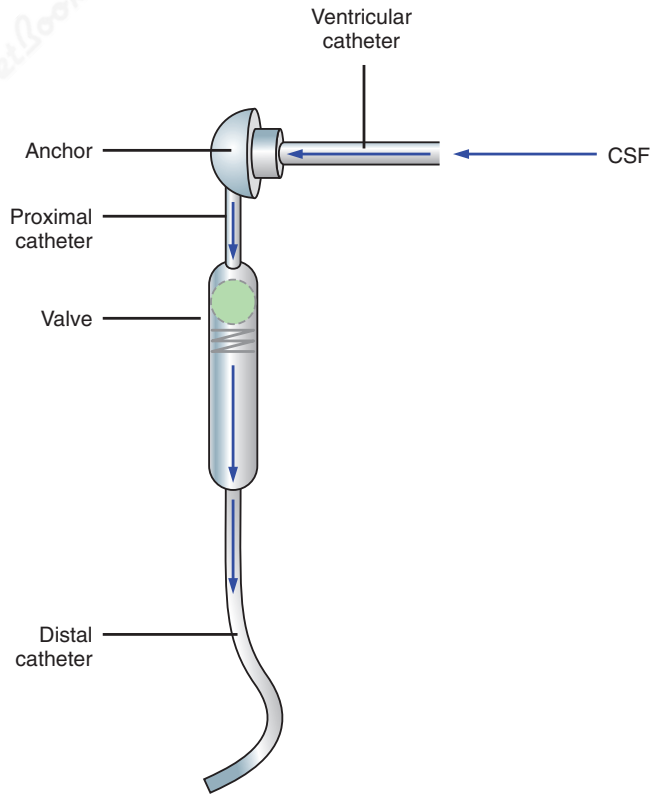

FIG. 39.10 Schematic of a typical ventriculoperitoneal shunt. *CSF,* Cerebrospinal fluid.

lateral plane. Lateral positioning of the caudal half of the patient facilitates the grid approach to the peritoneal cavity.

SURGICAL TECHNIQUE

Shave and prepare the head as described for rostrotentorial craniotomy (p. 1343). Also shave and prepare the entire lateral surface of the patient up to the level of the tuber coxae. For very small patients (e.g., Chihuahua, Yorkshire terrier), make two incisions: one curvilinear incision over the caudodorsal region of the parietal bone and one vertical incision caudal to the last rib (Fig. 39.11A). For larger patients (e.g., English bulldogs), make an additional incision approximately midway between these two incisions on the lateral thorax, if required. Use a high-speed drill to drill two holes in the parietal bone: one for the shunt and one for an anchoring suture. Incise the meninges over the area of shunt insertion with a No. 11 blade, and remove the small area of cerebrum underlying the meninges with a suction tip to access the lateral ventricle. Premeasure the amount of shunt to be inserted into the ventricle, and insert it into the dorsal aspect of the ventricle. After insertion of the rostral end of the shunt into the lateral ventricle, secure it with a Chinese finger-trap suture (see p. 923) via the anchor hole using 3-0 or 4-0 polypropylene (Prolene) suture (Fig. 39.11B). Perform a grid approach to the peritoneal cavity, and tunnel the distal end of the shunt from the cranial incision to the caudal incision using long Carmalt or Doyen forceps (Fig. 39.11C). After placement of the distal end of the shunt tubing into the peritoneal cavity, secure it to both the last rib and the abdominal musculature.

SUTURE MATERIALS AND SPECIAL INSTRUMENTS

Shunts were described previously under Surgical Treatment. A high-speed drill is needed to drill holes into the parietal bone. To secure the shunt, 3-0 to 4-0 nonabsorbable suture (e.g., polypropylene [Prolene]) is needed. A long Carmalt or Doyen forceps is used to tunnel the shunt. Baby or small Gelpi retractors facilitate the grid approach to the peritoneal cavity. A Matthew-Senn retractor or a spay hook in the flank incision (once the peritoneal cavity is entered) used to elevate the body wall helps with shunt insertion into the peritoneal cavity

POSTOPERATIVE CARE AND ASSESSMENT

Postoperative radiographs (Fig. 39.12) or a CT scan (Fig. 39.13) is performed to assess the accuracy of shunt placement. The patient is placed in a padded cage in an intensive care unit and is administered analgesics and antiseizure medications as needed.

PROGNOSIS

The prognosis for dogs and cats with congenital hydrocephalus is variable but is generally guarded to good with surgical management. In the author's experience, most severely clinically affected congenital hydrocephalic dogs treated medically do poorly. The prognosis for sustained clinical improvement in neurologic status after surgical shunting procedures varies in the literature from 50% to 90% for dogs. The success rate is approximately 75% to 80%. Potential postoperative surgical shunt complications in dogs and cats include shunt obstruction or dislodgment, mechanical damage to the shunt, and shunt infection. In one retrospective study of 36 hydrocephalic patients treated via ventriculoperitoneal shunt placement, 26 patients (72%) experienced improvement in clinical signs. In this study, most shunt-related complications and deaths occurred within the first 3 months of surgery, suggesting the need for particularly close monitoring of these patients during this postoperative time period.[7]

INTRACRANIAL ARACHNOID CYST

DEFINITION

IAC is a developmental brain disorder in which CSF is thought to accumulate within a split of the arachnoid membrane during embryogenesis. It is also termed an *intraarachnoid cyst* or *quadrigeminal cyst*.

GENERAL CONSIDERATIONS AND CLINICALLY RELEVANT PATHOPHYSIOLOGY

The developing neural tube is surrounded by a loose layer of mesenchymal tissue called *perimedullary mesh;* this tissue eventually becomes the pia and arachnoid layers of the meninges. In normal development, pulsatile CSF flow from the choroid plexuses divides the perimedullary mesh into pia and arachnoid layers, creating the subarachnoid space. It is postulated that some aberration of CSF flow from the choroid plexuses during this stage of development forces a separation within the forming arachnoid layer, eventually leading to the creation of an IAC. The intraarachnoid location of IACs in people has been demonstrated via light and electron microscopy. The mechanisms by which an IAC continues to expand with fluid are unknown,

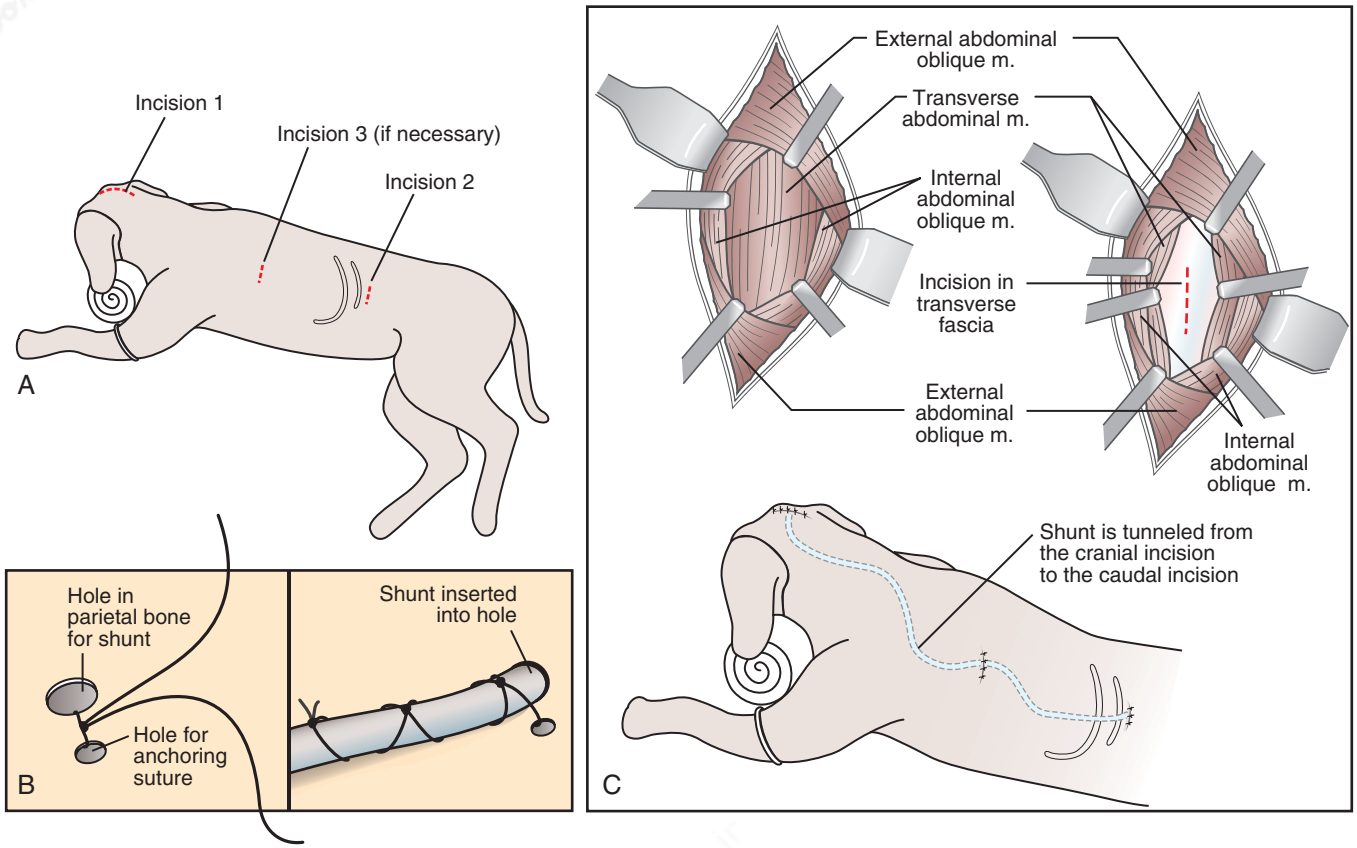

FIG. 39.11 (A) Surgical positioning and location of incisions for ventriculoperitoneal shunt (VPS) placement. (B), Insertion and anchoring of the rostral end of the VPS. (C) Grid approach to the peritoneal cavity following subcutaneous tunneling of the VPS.

FIG. 39.12 Lateral radiograph of a dog showing proper shunt placement.

but several theories have been proposed. Fluid may be secreted by arachnoid cells lining the cyst cavity. Evidence suggests that cells lining the IAC may have secretory capacity. Fluid movement into the cyst may also occur via an osmotic pressure gradient. Given that the fluid within the IAC is nearly identical to CSF, this theory is unlikely. In addition, cases in people in which small slits exist between the IAC and the subarachnoid space have been documented; these slits act as one-way valves, diverting CSF into the cyst during systole, which cannot return to the subarachnoid space during diastole.

Although IAC has been reported to occur in several locations in humans, all reported canine cases have been located in the caudal fossa. Because IAC is typically associated with the quadrigeminal cistern in dogs, these accumulations of fluid in this species are often called *quadrigeminal cysts.* Similar structures have been reported in cats. Also termed *intracranial intraarachnoid cyst,* IAC accounts for 1% of all intracranial masses in people and has been sporadically reported in dogs. IAC is often an incidental finding in humans; it has recently been suggested that this may also be the case for IAC in dogs.

DIAGNOSIS

Clinical Presentation

Signalment

A vast majority of reported IAC cases in dogs have been noted in small breeds, with a predominance of brachycephalic dogs. The breed most commonly reported is the shih tzu. A wide age

FIG. 39.13 Computed tomography image of a dog's head showing the rostral end of the ventriculoperitoneal shunt in the lateral ventricle.

range has been reported at clinical presentation for dogs with IAC, with an approximate average age of 4 years (range, 2 months–10 years).

History

The most common clinical signs seen with IAC are forebrain (including seizure activity) and/or central vestibular (cerebellovestibular) dysfunction. Dogs may also present with a primary complaint of neck pain.

Physical Examination Findings

Dogs with IAC typically do not have obvious structural abnormalities of the skull or divergent strabismus, as are seen in patients with congenital hydrocephalus. Clinical signs of vestibular dysfunction (e.g., head tilt, strabismus, nystagmus) may be present. Most patients appear to be in pain on palpation of the head and neck regions.

Diagnostic Imaging

IAC is typically diagnosed via CT, or preferably MRI. IACs can be visualized using ultrasound imaging (via foramen magnum, temporal window, and/or persistent bregmatic fontanelle), especially in younger dogs. The characteristic appearance of IAC is a large, well-demarcated fluid-filled structure, isointense with CSF spaces and located between the caudal cerebrum and the rostral cerebellum (Fig. 39.14A–B). Because IAC may be an incidental finding, it is important to rule out concurrent inflammatory disease (i.e., CSF examination). It is often difficult or impossible to discern whether IAC in the presence of another brain disorder is purely an incidental finding. Because the presence of a large, fluid-filled structure within the cranial vault likely decreases intracranial compliance, some IACs may be contributory, rather than an incidental finding. The degree of brain compression by the IAC as measured on MRI is predictive of whether the patient will display clinical signs of dysfunction due to the IAC.

FIG. 39.14 (A) Midsagittal and (B) axial T2-weighted magnetic resonance images of a dog with an intracranial arachnoid cyst.

Because this disorder is believed to represent a developmental abnormality of the intracranial ventricular CSF system, it may occur concurrently with other fluid abnormalities (e.g., congenital hydrocephalus). The cyst may or may not communicate with the remainder of the ventricular system. When evidence of IAC and signs of another disease (e.g., GME) are noted in the same patient, optimal response may entail treating both conditions.

Laboratory Findings

As with congenital hydrocephalus (see p. 1348), laboratory findings are normal when IAC is the primary condition.

DIFFERENTIAL DIAGNOSIS

The differential diagnoses for IAC are essentially the same as for congenital hydrocephalus (see p. 1348). In IAC cases that exhibit obvious vestibular dysfunction, disorders that tend to cause vestibular dysfunction (e.g., GME) are higher on the differential diagnosis list. Additionally, for those IAC dogs that exhibit signs of cerebellar dysfunction, disorders such as cerebellar vermian hypoplasia (Dandy-Walker syndrome) and cerebellar abiotrophy need to be considered. If clinical signs of cerebellar dysfunction are of acute onset, cerebellar infarct should be considered a differential diagnosis.

MEDICAL MANAGEMENT

Medical treatment for IAC is identical to that described for congenital hydrocephalus (e.g., glucocorticoids, diuretics, anticonvulsants if indicated; see p. 1349). Dogs with IAC tend to respond initially to medical therapy, but the response is often temporary.

SURGICAL TREATMENT (Video 39.3)

Preoperative Management

See p. 1338 for preoperative management of the brain surgery patient.

Anesthesia

See p. 1340 for anesthetic management of the brain surgery patient.

Surgical Anatomy

See Chapter 38 and p. 1342 for surgical anatomy of the brain and skull.

Positioning

Patient positioning is identical to that described for congenital hydrocephalus (see p. 1349).

SURGICAL TECHNIQUE

Surgical management of IAC in people is typically achieved via cyst fenestration or cystoperitoneal shunt placement. Both procedures have been reported in dogs with IAC. Most IACs in dogs are large enough that they can be accessed for fenestration through a caudally based rostrotentorial approach or a suboccipital approach. If extensive resection of the cyst wall is planned, this may be difficult to achieve with the limited exposure of a suboccipital approach. A combined rostrotentorial/suboccipital approach with sacrifice of the transverse sinus and insertion of a cystoperitoneal shunt may be preferred.

With the exception of the extent of the craniotomy defect and placement of the rostral end of the shunt, the procedure is identical to that described for congenital hydrocephalus. *For placement of the rostral end of the shunt in IAC cases, create a wide caudolateral craniotomy, incorporating the creation of a rostrotentorial and a suboccipital skull defect. Sacrifice the transverse sinus between these two defects and occlude it with bone wax.*

SUTURE MATERIALS AND SPECIAL INSTRUMENTS

See congenital hydrocephalus (see p. 1350).

POSTOPERATIVE CARE AND ASSESSMENT

As with congenital hydrocephalus, postoperative imaging is performed to assess the accuracy of shunt placement (Fig. 39.15). The patient is placed in a padded cage and is administered analgesics and antiseizure medications (if necessary).

PROGNOSIS

The success rate for surgical management of IAC appears to be high in humans and in dogs, and whether fenestration or cystoperitoneal shunting is the preferred procedure remains controversial for both species.

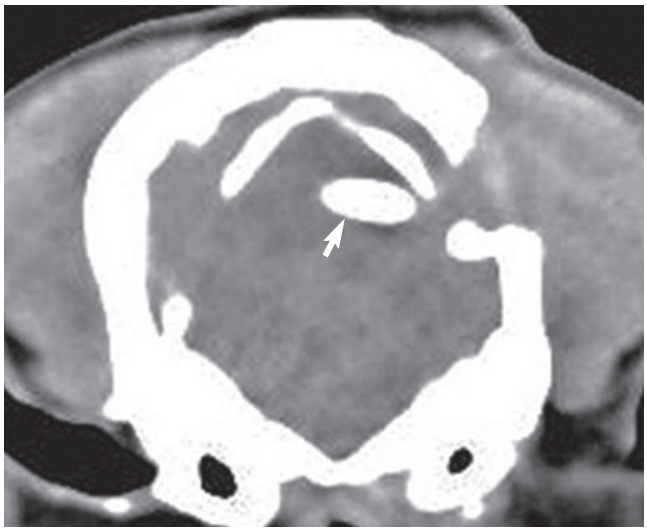

FIG. 39.15 Postoperative axial computed tomography image, demonstrating shunt position *(arrow)* and collapse of the intracranial arachnoid cyst.

CHIARI-LIKE MALFORMATION

DEFINITION

CLM, a disorder that is believed to be the canine analog of Chiari type I malformation of people, is characterized by malformation of the supraoccipital bone. Similar to the human disorder, the cranial cavity is too small to accommodate the contents of the caudal fossa (cerebellum and brain stem), resulting in overcrowding of the cerebellomedullary region of the brain (Fig. 39.16A–B).

GENERAL CONSIDERATIONS AND CLINICALLY RELEVANT PATHOPHYSIOLOGY

Increasing evidence suggests that CLM in dogs is a condition in which the entire skull is malformed, although the caudal aspect is most obviously abnormal on MRI, which often reveals a visible abnormality of the supraoccipital bone that causes an indentation of the caudal cerebellum. Additionally, an interruption of the dorsal subarachnoid space is typical at the level of the cervicomedullary junction. Herniation of the caudal aspect of the cerebellum through the foramen magnum is also often appreciable on sagittal magnetic resonance (MR) images in CLM cases (Fig. 39.17). Overall, CLM appears to represent a mismatch between the brain parenchyma residing within the cranial cavity and the volume available within this cavity to accommodate the parenchyma. In other words, there is too much brain parenchyma in too small a space; this is more apparent in the caudal fossa, but is an overall brain parenchyma/intracranial volume mismatch in affected dogs. Most dogs with CLM have cervical syringomyelia (SM) (fluid accumulation within the spinal cord parenchyma) evident on MRI (Fig. 39.18). The majority of dogs that have their entire spine imaged (i.e., not just the cervical region as is commonly done in some practices) have syrinx cavities in the thoracic and lumbar spinal cord regions, as well as in the cervical region. SM in this condition is believed to be secondary to a pressure differential between intracranial and spinal components,

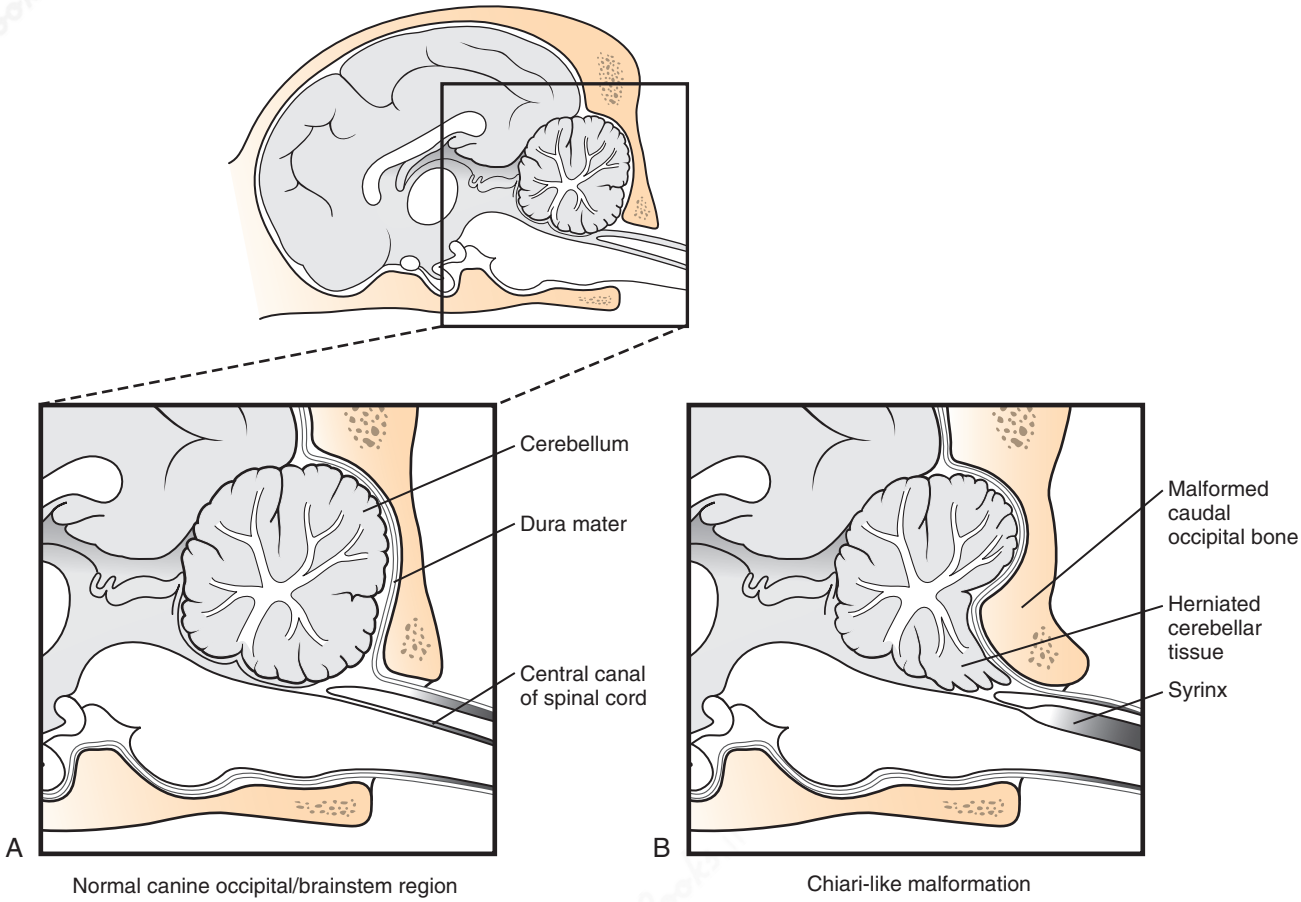

FIG. 39.16 (A) Schematic illustration of the normal shape of the caudal occipital region. (B) The typical shape of this region in a dog with Chiari-like malformation.

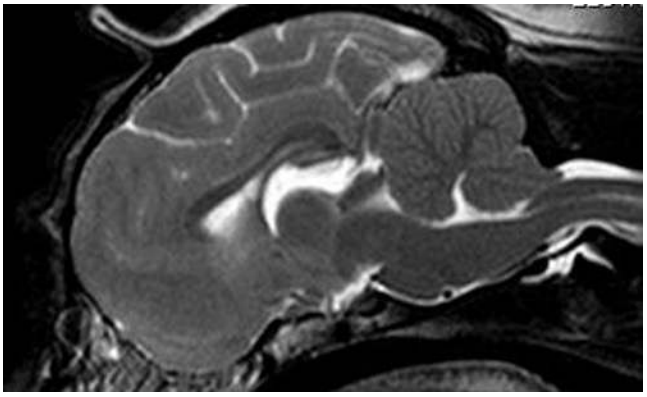

FIG. 39.17 Sagittal T2-weighted brain image of a dog with Chiari-like malformation, showing cerebellar herniation through the foramen magnum.

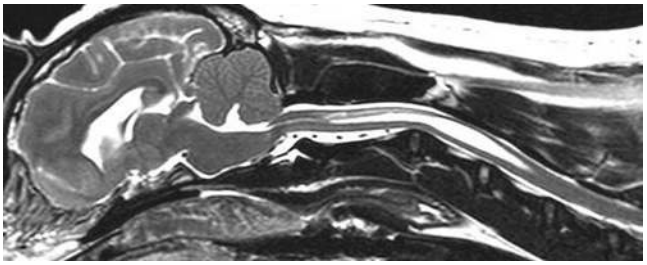

FIG. 39.18 Sagittal T2-weighted cervical spine image of a dog with Chiari-like malformation showing extensive syringomyelia in the cervical spinal cord.

because of abnormal flow dynamics at the cervicomedullary junction (see Chapter 40).

DIAGNOSIS

Clinical Presentation

Signalment

CLM is typically encountered in small-breed dogs; the Cavalier King Charles spaniel (CKCS) is the most commonly affected breed. Other breeds affected by this disorder include Brussels griffon, miniature poodle, Yorkshire terrier, Maltese, Chihuahua, bichon frise, Staffordshire terrier, pug, shih tzu, miniature dachshund, miniature pinscher, French bulldog, Pekingese, and Boston terrier. Anecdotal reports describe this disorder in several brachycephalic cats. The typical age range at presentation appears to have changed over time, with many dogs developing clinical signs within the first year of life. In general, although the age range at clinical presentation is broad, most dogs present by the time they are 4 years old. Dogs that present at younger than 2 years of age often have more severe clinical signs than older dogs. In recent years, we have seen an increasing number of younger patients (<1 year of age); whether this trend reflects

increasing severity of the disorder with subsequent generations, increased awareness of the veterinary community and hence earlier diagnosis, or a combination of these two factors is unknown.

History

The most salient historical complaint for this disorder is pain, which is usually localized to the neck region. Incessant scratching activity, typically in the head and neck region, is a common historical complaint that is usually evident in the CKCS breed. Other historical complaints include balance loss, head tilt, tetraparesis, and scoliosis.

Physical Examination Findings

Clinical signs are variable, but the most consistent clinical feature is pain (hyperesthesia). Some of the clinical signs are attributable to constriction at the cervicomedullary junction, but many are due to SM. Clinical signs of this disease include neck pain, back pain, vestibular dysfunction, cervical myelopathy, incessant scratching activity, and scoliosis. In people with Chiari type I malformation, one of the most frequent clinical features is a severe suboccipital headache. Almost all dogs with CLM that the author has examined exhibit dramatic evidence of hyperesthesia when the caudal occipital region is lightly palpated with the thumb and index finger. Cervical myelopathy with associated neck pain and cerebellovestibular dysfunction (e.g., strabismus, decreased menace response with normal vision, head tilt, nystagmus) are most commonly encountered. In most cases, cerebellovestibular dysfunction is revealed during a neurologic examination and has not necessarily been observed by the pet owner. Many dogs with CLM have decreased to absent menace responses with normal vision, as well as varying degrees of positional ventrolateral strabismus. Scratching activity appears to be a very consistent clinical feature of CLM in the CKCS breed but is not as prevalent in other breeds with CLM. An unusual and distinctive feature of the scratching activity associated with CLM in dogs is that these patients typically do not make contact with the skin while scratching at the head and shoulder regions, so-called "phantom scratching." Scratching often occurs only on one side. Facial rubbing (pawing at the face and/or rubbing against objects) is encountered in some dogs and is considered to be a form of pain and/or paresthesia. Spinal hyperpathia (typically cervical), scratching activity, and scoliosis are all generally believed to be related to interference of the syrinx cavity with ascending sensory pathways in the spinal cord. Scratching activity and neck discomfort are often exacerbated by abrupt weather changes, stress or excitement, and physical contact with the neck/shoulder region (e.g., collar). Some dogs will experience pain during defecation. The presence of both pain and scoliosis is correlated with syrinx width in CKCS dogs with SM secondary to CLM. Some of the neck pain may be directly related to constriction at the cervicomedullary junction.

Diagnostic Imaging

The diagnosis of CLM is made by MRI, which is also the preferred imaging modality for diagnosing SM. The malformation is best visualized on a midsagittal view (preferably T2 weighted), which includes the caudal fossa and the cranial cervical spinal cord. Consistent findings on MRI associated with CLM include attenuation/obliteration of the dorsal subarachnoid space at the cervicomedullary junction and rostral displacement of the caudal cerebellum by the occipital bone (Fig. 39.19). A 2015 retrospective MRI study of brachycephalic dogs without clinical signs attributable to CLM/SM concluded that rostral cerebellar displacement is often (44%) present incidentally and is likely a normal anatomic variant associated with the brachycephalic skull. This MR feature also became more prominent with increased head extension.[8] Other common MRI findings in CLM include SM (usually C2 level caudally), herniation of the caudal cerebellum through the foramen magnum, and a kinked appearance of the caudal medulla. Phase-contrast MRI (cine-MRI) is often used to measure CSF flow in humans with Chiari type I malformation and has been evaluated for use in dogs with CLM. Occasionally, dogs with MRI findings consistent with CLM will have evidence of other congenital disorders, such as intracranial arachnoid (quadrigeminal) cyst, malformation/malarticulation of the C1 and/or C2 vertebrae, and hydrocephalus. Most small-breed dogs normally have large lateral ventricles as a breed characteristic (ventriculomegaly) and are not hydrocephalic.

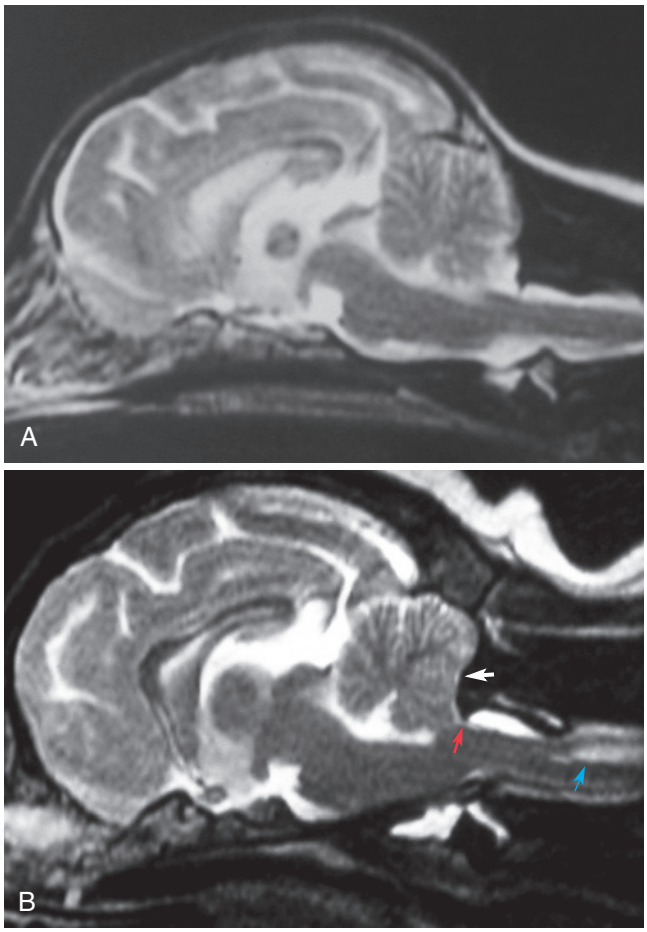

FIG. 39.19 Midsagittal T2-weighted brain magnetic resonance image of (A) a normal small-breed dog and (B) a dog with Chiari-like malformation (CLM). In the CLM dog, note rostral displacement of the caudal cerebellum by the supraoccipital bone *(white arrow)*, obliteration of the dorsal subarachnoid space at the cervicomedullary junction *(red arrow)*, and the syrinx cavity starting at the level of the C2 cervical vertebra *(blue arrow)*.

Laboratory Findings

In the absence of concurrent disease processes, CSF analysis is usually normal; occasionally, a mild mononuclear pleocytosis will be apparent.

DIFFERENTIAL DIAGNOSIS

In addition to the questionable significance of some of the MR "abnormalities" associated with CLM (some may be breed-associated normal variants), clinical diagnosis of this disorder is made further complicated by the fact that a large subset of dogs with definitive MRI evidence of CLM and SM display no obvious clinical signs associated with their anatomic abnormalities. It is important to realize that, especially in the CKCS breed, other conditions may account for some, or all, of the clinical signs identified. More than 40% of CKCS dogs with MRI evidence of CLM/SM are asymptomatic for the disorder, according to their owners. The severity and rate of progression of CLM in dogs are variable, ranging from asymptomatic (i.e., finding evidence of CLM while imaging for some other reason, or as a breed screening study) to extreme pain and debilitation with rapid worsening over a short period. Additionally, some dogs with CLM have other, unrelated concurrent disorders (e.g., disc extrusion, inflammatory brain disease) that could explain observed clinical signs. In such situations, it may be difficult to discern whether CLM is the main problem or is contributory or an incidental finding. Finally, other disorders of the craniocervical junction (see Chapter 40) can occur concurrently with or can be mistaken for CLM in dogs.

MEDICAL MANAGEMENT

Medical therapy for dogs with CLM generally falls into three categories: analgesic drugs (implies relief of dysesthesia/paresthesia also), drugs that decrease CSF production, and glucocorticoid therapy. The most useful drug available for relief of scratching activity associated with SM has been gabapentin (see Table 39.1). It has been shown that neuropathic pain is accentuated over time owing to upregulation of α2δ-1 subunit voltage-gated calcium channels in dorsal root ganglion neurons and dorsal horn nociceptive neurons of the spinal cord. Gabapentin and the newer gabapentin analog, pregabalin, are believed to exert their antinociceptive effects by selectively binding to the α2δ-1 subunit and inhibiting calcium influx in these neurons. Side effects of gabapentin are minimal, usually restricted to mild sedation, pelvic limb ataxia, and weight gain.

Pregabalin (see Table 39.1) may be a more effective drug in relieving pain and scratching activity in CLM dogs. Because the half-life of elimination of pregabalin is nearly twice as long as that of gabapentin, twice a day dosing is possible. It is important to start at the low end of the dose range to avoid side effects of sedation and ataxia. Orally administered opiate drugs are sometimes helpful in alleviating neck and head pain in CLM dogs. Oral tramadol (2–4 mg/kg every 8–12 hours) may also be useful. A number of drugs aimed at decreasing CSF production have been used in CLM patients in an effort to diminish CSF pulse pressure. All information regarding efficacy of these drugs is anecdotal. They include omeprazole (a proton pump inhibitor), acetazolamide (a carbonic anhydrase inhibitor), and furosemide (a loop diuretic). More specific information regarding these drugs is covered in the congenital hydrocephalus discussion. Prednisolone is often used in medical management of CLM. Potential benefits include antiinflammatory effects, decreased CSF production, and decreased substance P (a nociceptive neurotransmitter) expression in spinal cord dorsal horn neurons. An initial anti-inflammatory dose of prednisolone (0.5 mg/kg orally every 12 hours) is often effective in controlling clinical signs. This dose should be tapered, if at all possible, to an every-other-day schedule within the first month of therapy. In most cases of CLM, medical therapy will diminish the severity of clinical signs, but resolution is unlikely.

SURGICAL TREATMENT (Videos 39.4 and 39.5)

Preoperative Management

See p. 1338 for preoperative management of the brain surgery patient.

Anesthesia

See p. 1340 for anesthetic management of the brain surgery patient. A guarded endotracheal tube should be used because of the extreme neck flexion often required for this procedure.

Surgical Anatomy

See Chapter 38 and p. 1342 for surgical anatomy of the brain and skull.

Positioning

Positioning is as described for suboccipital craniotomy (p. 1344). Because the head needs to be ventroflexed approximately 90 degrees, a guarded endotracheal tube should be used.

SURGICAL TECHNIQUE

In people with symptomatic Chiari type I malformation, surgical therapy is considered the treatment of choice, and FMD is the preferred surgical procedure. Adjunctive surgical procedures are occasionally performed in people who have had a suboptimal response to FMD; such procedures usually involve placement of a shunt to divert SM fluid from the spinal cord region to another location for absorption (e.g., pleural or peritoneal cavity, subarachnoid space). Although a high degree of success has been associated with surgical management of Chiari type I malformation in people, the reoperative rate varies from 8% to 30% for FMD; the most common problem necessitating reoperation is excessive scar tissue formation at the FMD site, causing compression at the cervicomedullary junction and effectively recreating the original disease state.

CLM is a surgical disorder. Based on more than 100 operated cases with long-term (i.e., more than 3 years) follow-up, the preferred surgical procedure for treatment of CLM in dogs is FMD with titanium mesh/PMMA cranioplasty. This procedure involves a suboccipital craniotomy and laminectomy of C1, with subsequent placement of a titanium mesh/PMMA plate on titanium screw anchor posts inserted around the circumference of the occipital bone defect (Fig. 39.20A–B). *Once the FMD is completed, incise the meninges (dura/arachnoid) on the midline and resect the meningeal tissue in the region of the FMD.* There is typically a fibrous band of tissue at the cervicomedullary junction that may be partially ossified. *Transect this band carefully with a probe (Gross ear hook and spoon) and a sharp No. 11 blade. Drill four to six guide holes in the occipital bone around the periphery of the skull defect using a 1.1-mm drill bit (Fig. 39.21A). Insert self-tapping 6-mm long (1.5-mm wide) screws into the guide holes for an approximate depth of 2 to 3 mm (Fig. 39.21B). Release the dog's head from the flexed position and reposition it at a normal resting angle. Fashion the skull plate using titanium mesh and PMMA and fix it to the back of the skull, using the titanium screw heads as anchor posts for the PMMA (Fig. 39.21C). Shape the plate somewhat like a guitar pick with the wide end of the pick toward the occiput. Apply only a thin layer of PMMA to both*

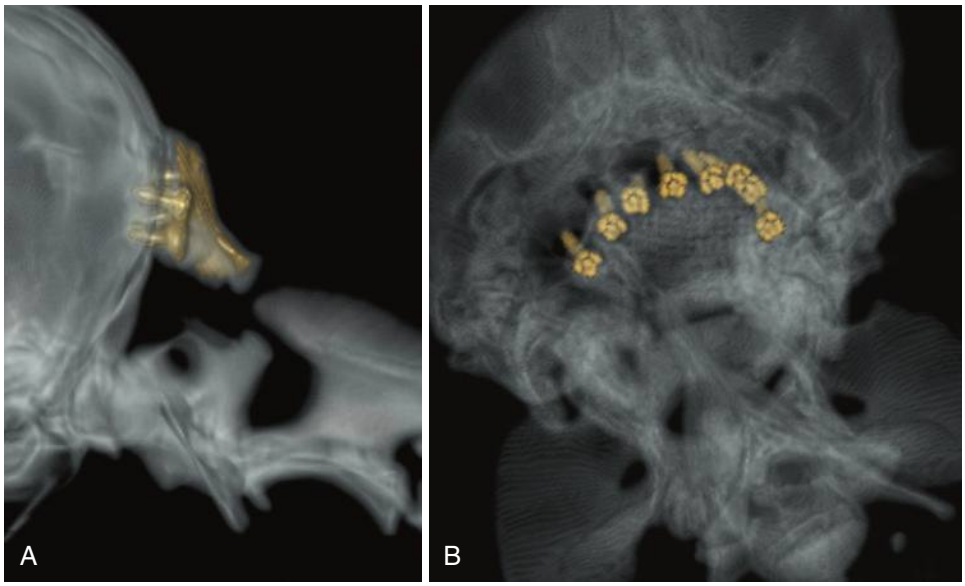

FIG. 39.20 (A) Lateral and (B) caudal three-dimensional reconstructed computed tomography postoperative views of a dog's skull following foramen magnum decompression with cranioplasty for Chiari-like malformation.

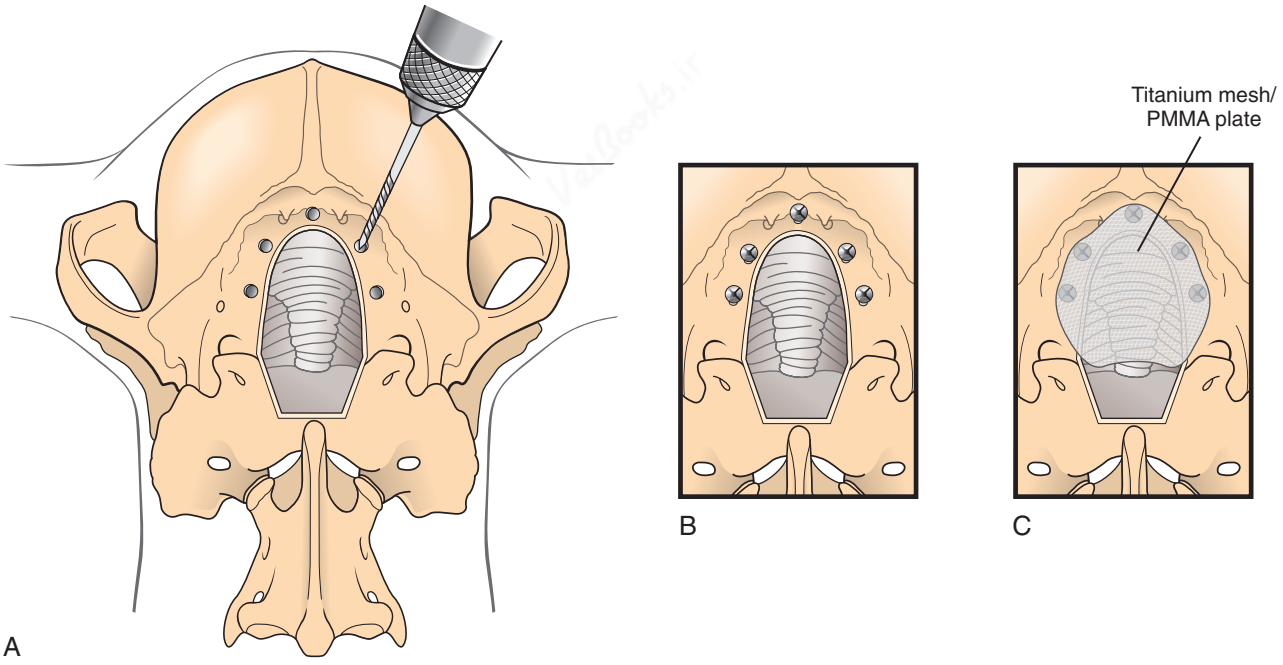

FIG. 39.21 (A) Typical pattern of guide hole placement for titanium screws. (B) Placement of self-tapping titanium screws in guide holes. (C) Placement of titanium mesh/polymethylmethacrylate plate to the foramen magnum decompression site. *PMMA,* Polymethylmethacrylate.

surfaces of the plate, with some PMMA extending beyond the edges of the titanium mesh to adhere to the titanium screw heads. Extend the caudal aspect of the plate slightly over the dorsal defect of C1; curve the tail aspect of the plate dorsally to avoid impinging on the medulla or the cranial cervical spinal cord. Close the skin routinely.

SUTURE MATERIALS AND SPECIAL INSTRUMENTS

A high-speed air drill, titanium mesh, titanium screws, and PMMA are required for this procedure. The drill guide holes can be made by using a minidriver or a specialized high-speed drill with a 1.1-mm drill bit attachment.

POSTOPERATIVE CARE AND ASSESSMENT

The patient is placed in a padded cage and analgesics are administered (e.g., fentanyl continuous-rate infusion; see p. 144). Patients generally require some form of oral analgesic therapy for 1 to 2 weeks after surgery. Proper plate application is confirmed via radiographs or (preferably) CT before anesthetic recovery.

PROGNOSIS

The short-term surgical success (sustained improvement of neurologic status and/or pain/scratching relief) rate with FMD in dogs with CLM is approximately 80%, whether or not adjunctive cranioplasty is performed. There appears to be an inverse relationship between the length of time clinical signs are present before surgical intervention and the extent of postoperative improvement. Unfortunately, there appears to be a disease relapse rate ranging from 25% to 47% of cases treated with FMD alone; most of these relapses are suspected to be due to excessive postoperative scar tissue formation at the FMD site. After surgery, clinical signs of pain are routinely relieved, but scratching activity tends to persist. A cranioplasty procedure (based on a similar procedure used in human FMD surgery) was developed by the author and colleagues to discourage excessive postoperative scar tissue from recompressing the operative site. Our most recent analysis of more than 100 cases of FMD with cranioplasty determined the reoperative rate to be 7% (unpublished data). A 2015 report described long-term (1- to 3-year follow-up) success in 23 dogs with CLM/SM treated via FMD with duraplasty (using lyophilized swine submucosa) and autogenous fat grafting; the authors of this study reported some level of improvement in 94% of patients.[9]

Little information is available regarding the prognosis for CLM in dogs treated medically alone. Most dogs with CLM will respond favorably to medical therapy, although in many cases this response is temporary. In general, between one-third and one-half of dogs symptomatic for CLM/SM seem to worsen over 1 to 2 years from the time of diagnosis, based on prior small studies and the authors' experience. In one larger, long-term prospective study of 48 CKCS dogs that evaluated the response to nonsurgical (medical only) management over a mean time period of 39 months, 25% of patients either remained static or improved, whereas 75% of the dogs deteriorated clinically over time. Approximately 15% of the dogs were euthanized due to clinical signs of severe neuropathic pain.[10] Although the surgical success rate appears generally favorable for CLM in dogs, the recurrence rate due to excessive postoperative scar tissue formation has been unacceptably high with FMD alone. It appears that cranioplasty and duraplasty have improved the success rate of FMD, but no surgical procedure has yet been demonstrated to consistently eliminate clinical signs associated with Chiari malformation in humans or dogs.

BRAIN TUMORS

DEFINITIONS

Brain tumors include neoplastic diseases involving the brain, including those arising from the brain and meningeal coverings *(primary brain tumors),* and those arising from local or distant (i.e., metastatic) anatomic structures *(secondary brain tumors)*.

GENERAL CONSIDERATIONS AND CLINICALLY RELEVANT PATHOPHYSIOLOGY

A discussion of the mechanisms involved in cancer development is beyond the scope of this textbook. Brain tumors cause clinical signs of disease primarily by physically impinging on neighboring brain tissue and increasing ICP. Peritumoral edema adds to this phenomenon. Brain tumors may cause brain compression and increased ICP via obstructive hydrocephalus and hemorrhage, both of which can lead to rapid exacerbation of neurologic dysfunction. Primary brain tumors are commonly encountered in dogs and cats. In both species, meningioma is the most commonly reported tumor. Gliomas (e.g., astrocytoma, oligodendroglioma) are frequently reported in dogs and are occasionally reported in cats. Other primary brain tumors less commonly reported in dogs include choroid plexus tumor, primary CNS lymphosarcoma, primitive neuroectodermal tumor (which typically includes neuroblastoma), primary CNS histiocytic sarcoma (also termed *malignant histiocytosis*), and vascular hamartoma. Other primary brain tumors occasionally encountered in cats include, in addition to gliomas, ependymomas, olfactory neuroblastomas, and choroid plexus tumors. Case reports of medulloblastomas in both dogs and cats usually involve the cerebellum. Secondary brain tumors in dogs and cats include hemangiosarcoma, pituitary tumor, lymphosarcoma, metastatic carcinoma, and invasive nasal/frontal sinus tumor.

DIAGNOSIS

Clinical Presentation

Signalment

Dogs and cats diagnosed with brain tumors tend to be older. The median age for dogs with primary brain tumors is approximately 9 years, and for cats it is over 10 years of age. In general, large-breed dogs tend to develop brain tumors more commonly than small-breed dogs. Golden retrievers and boxer dogs appear to be predisposed to primary brain tumors. Golden retrievers are prone to developing meningiomas, whereas boxer dogs and other brachycephalic breeds (e.g., Boston terriers) are more likely to be diagnosed with glioma. More than half of brain tumors diagnosed in cats are meningiomas. In both dogs and cats, patients with meningiomas tend to be somewhat older at diagnosis than those with other brain tumors types. In dogs, astrocytomas are more likely than other primary brain tumors to occur in the diencephalon and cerebellum. Choroid plexus tumors may occur in the lateral, third, or fourth ventricle. The mean age of patients with secondary brain tumors is similar to that for patients with primary brain tumors (9–10 years). Mixed breed dogs are most commonly affected, followed by golden retrievers and Labrador retrievers.

History

Historical complaints vary according to species, tumor location, and tumor aggressiveness. Brain tumors are more commonly located in the rostral fossa; therefore abnormal behavior and seizures are the most common clinical complaints. Seizure activity is the most common clinical complaint associated with canine brain tumors, whereas behavior change is the most common clinical complaint associated with feline brain tumors. With slow-growing primary brain tumors (i.e., meningioma), the owner may retrospectively (i.e., after the diagnosis is attained) realize that the pet had been exhibiting signs of altered behavior

for a protracted period (sometimes up to a year); initially, such vague clinical signs may be attributed by pet owners to "old age." Clinical signs associated with tumors in the caudal fossa usually include loss of balance and abnormal behavior (usually obtunded mental status).

Physical Examination Findings

Neuroanatomic localization of the brain tumors is typically reflected in the signs of neurologic dysfunction exhibited by the patient. However, it is not uncommon for dogs and cats with solitary brain neoplasms to display dysfunction of more than one region of the brain (i.e., combination of forebrain and brainstem dysfunction); this phenomenon is likely due to the size of some of these tumors and to the extent of peritumoral edema. Because approximately half of canine primary brain tumors occupy more than one anatomic region of the brain, it is possible to falsely conclude, based on neurologic examination, that a patient with a solitary brain mass has multifocal disease.

NOTE Nearly one-fourth of dogs with primary brain tumors have concurrent, unrelated neoplasia (e.g., pulmonary carcinoma, hemangiosarcoma), most of which involves the thoracic or abdominal cavity. Be certain to screen for concurrent unrelated neoplasia (via thoracic radiography and abdominal ultrasonography) before pursuing advanced diagnostics and definitive therapy for brain tumors.

In cats with a primary brain tumor, nonspecific presenting clinical signs (i.e., signs not obviously referable to neurologic dysfunction) occur in more than 20%. These clinical signs include lethargy, inappetence, and anorexia. Multiple intracranial meningiomas have been reported to occur in cats with some frequency (approximately 17%). Most dogs and cats with brain tumors display evidence of head and neck pain on palpation.

Diagnostic Imaging

MRI is the preferred imaging modality for the diagnosis of canine and feline brain tumors. In general, meningiomas appear as extraaxial, uniformly contrast-enhancing masses with broad-based attachment to the skull and well-delineated borders (Fig. 39.22), whereas gliomas tend to be intraaxial, nonuniformly contrast-enhancing masses with indistinct margins between mass and normal brain tissue (Fig. 39.23). Meningeal contrast enhancement evident on MRI of the brain has been described but is not specific for brain tumors. The "dural tail" sign is an MRI feature typically associated with meningiomas, in which a contrast-enhancing meningeal-associated "tail" is seen extending from the main tumor mass (Fig. 39.24).

Laboratory Findings

Because CSF analysis tends to yield fairly nonspecific information in brain tumor cases, obtaining CSF from dogs and cats when the imaging is highly supportive of a brain tumor may not be worthwhile.

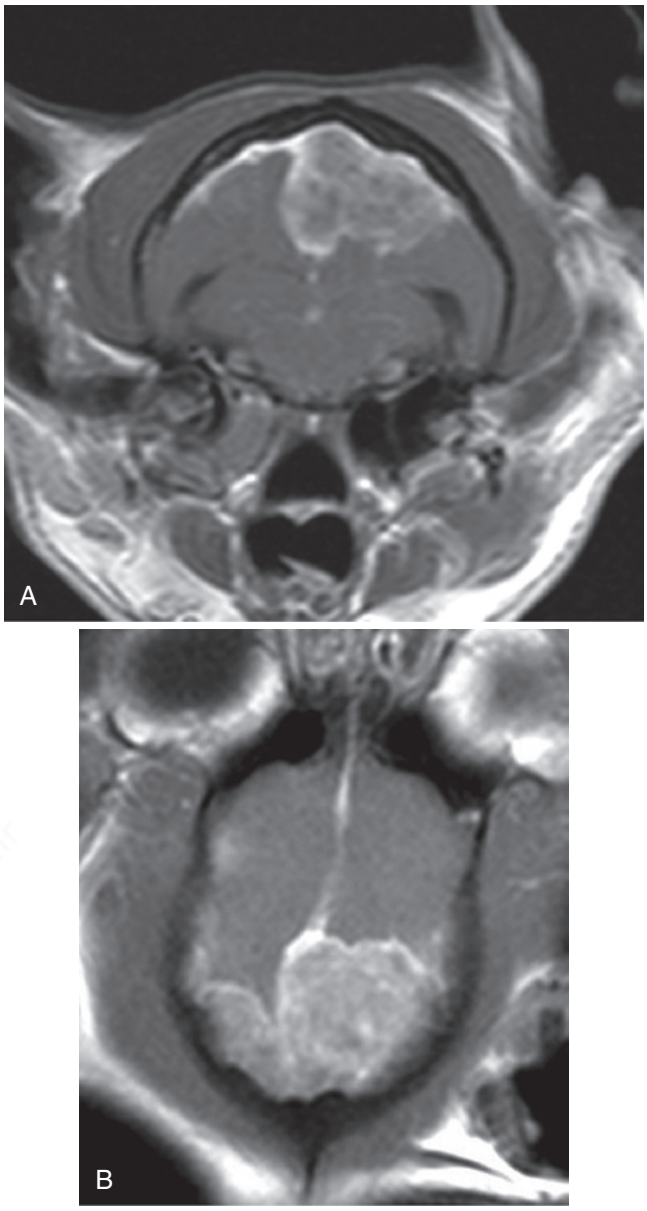

FIG. 39.22 (A) Axial and (B) dorsal (coronal) T1-weighted with contrast magnetic resonance brain images of a cat with a cerebral meningioma.

DIFFERENTIAL DIAGNOSIS

Differential diagnoses for brain tumors in dogs and cats depend primarily on clinical signs and neuroanatomic localization. For example, in an older dog with recent onset of seizures and no neurologic deficits, the main differential diagnosis other than brain tumors is late-onset idiopathic epilepsy. In an older dog with clinical signs of dementia and circling behavior, a major differential diagnosis would be the canine analog of Alzheimer's disease of people: canine cognitive dysfunction. Other differential diagnoses in suspected brain tumor patients include metabolic encephalopathy, inflammatory/infectious disease (e.g., GME), toxin exposure, and ischemic/vascular events (in cases with acute onset of neurologic dysfunction).

MEDICAL MANAGEMENT

Medical management for dogs and cats with brain tumors may be supportive or definitive. Supportive therapy refers to treatment that addresses the secondary effects of a tumor, not the tumor itself. Such therapy includes low doses of oral prednisolone (e.g.,

FIG. 39.23 Axial T2-weighted magnetic resonance image of a dog with an intracranial astrocytoma.

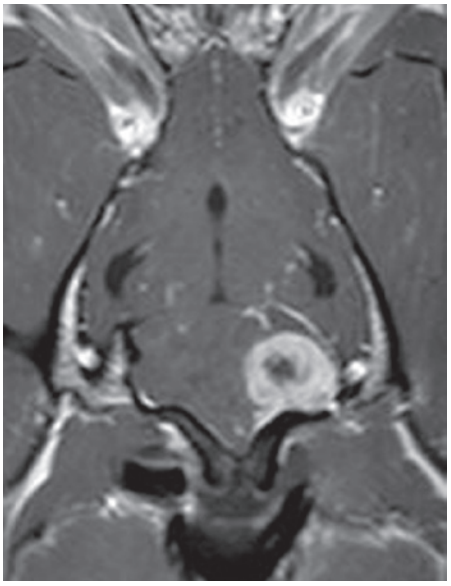

FIG. 39.24 Dorsal (coronal) T1-weighted with contrast magnetic resonance image of a cerebellar meningioma in a dog with a dural tail.

0.5 mg/kg every 12 hours) to decrease peritumoral edema and antiseizure medication, if necessary (see Table 39.1). Definitive medical therapy is directed at killing tumor cells and includes radiation therapy and chemotherapy. The traditional or conventional method of delivering definitive megavoltage radiation therapy of brain tumors is administration of fractionated daily doses of 2.5 to 4 Gy on a Monday through Friday (once a day) schedule for 4 weeks. Protocols vary, but most involve administration of a total cumulative dose in the range of 30 to 50 Gy. In recent years, stereotactic radiation therapy techniques (e.g., Gamma knife, Cyberknife) have been gaining in popularity; these methods of more anatomically precise (less chance of inadvertent radiation delivery to surrounding normal parenchyma) radiation delivery allow for fewer treatment sessions (one to five treatments) to deliver the same total dose as with traditional fractionated radiation therapy.

Oral chemotherapy is often used to treat dogs with brain tumors. Hydroxyurea is used for meningiomas and lomustine for gliomas (Box 39.1). Bone marrow suppression and delayed dose-related hepatotoxicity may occur with oral lomustine use. Although hepatoxocity has been reported in approximately 6% of cases, it may occur more frequently; this drug should be used cautiously. Hydroxyurea is an oral chemotherapeutic agent with efficacy against intracranial meningiomas in people (see Box 39.1). Proposed mechanisms of action of hydroxyurea include induction of tumor cell apoptosis and inhibition of ribonucleotide diphosphate reductase (with subsequent interference with DNA synthesis). Mild to moderate bone marrow suppression is a potential side effect of hydroxyurea use in people; to date, this side effect has not been an important issue in dogs.

BOX 39.1 Medical Therapy for Brain Tumors in Dogs

Prednisolone

0.5–1.0 mg/kg PO q12h; may be able to taper to every other day after 1 month if treated with chemotherapy and/or radiation therapy

Hydroxyurea

20 mg/kg PO q24h

Lomustine

60 mg/m^2 PO every 6–8 wk. Potential adverse effects include bone marrow suppression and hepatotoxicity.

Megavoltage Radiation

2.5–4.0 Gy administered to tumor or tumor bed (postoperatively) for 15–20 treatments (total of 30–50 Gy) vs. stereotactic radiation therapy (total dose delivered in 1–5 treatments)

Antiseizure Drugs

See Table 39.1.

SURGICAL TREATMENT

Preoperative Management

See p. 1338 for preoperative management of the brain surgery patient.

Anesthesia

See p. 1340 for anesthetic management of the brain surgery patient.

Surgical Anatomy

See Chapter 38 and p. 1342 for surgical anatomy of the skull and brain.

Positioning

See descriptions of specific surgical approaches (pp. 1342–1344) for patient positioning.

SURGICAL TECHNIQUE

Surgical approaches to the brain necessary to access brain tumors in various locations are discussed on pp. 1342 to 1344.

Once the brain is exposed, sharply incise the meninges (dura/arachnoid) with a No. 11 blade, over the region of the mass using a combination of a probe (e.g., Gross ear hook and spoon) and a No. 11 blade. Create a meningeal flap using Bishop-Harmon forceps (no teeth) and tenotomy scissors to assist with tumor removal and to decrease bleeding tendencies (compared with incising the meninges directly over the mass). Incise below the mass, create a flap, and pull it dorsally. Using a combination of a probe and a lens loop, find a plane between the tumor and surrounding brain tissue, and attempt to free the tumor edges from the brain for the entire circumference of the mass. When applying traction to a tumor, always direct the traction away from the brain to minimize brain trauma and inadvertent increases in ICP. Use moistened, lint-free cottonoid sponges on the brain surface to keep it moist and decrease surface hemorrhage. In some firm tumors, place a stay suture into the mass and use it to help pull the mass outward while dissecting around its medial aspect. In some tumors (e.g., infiltrative tumors, tumors near the dorsal sagittal sinus), it may be beneficial to use a CUSA to assist in mass removal. *Once the tumor is removed, resect abnormally colored tissue in the tumor bed with suction or a CUSA. Control tumor bed hemorrhage with bipolar cautery, as well as placement of moistened Gelfoam and/or Surgicel into the defect. Do not close the incised or resected meninges unless the frontal sinus has been entered.* See Standard Surgical Approaches to the Brain (pp. 1342–1344) for a description of skull reconstruction. *Close subcutaneous tissues and skin routinely.*

SUTURE MATERIALS AND SPECIAL INSTRUMENTS

In addition to a high-speed air drill, instruments that are essential for successful brain tumor removal include probes (e.g., Gross ear hook and spoon), lens loops, bipolar cautery, and Bishop-Harmon forceps. A CUSA may be helpful for removal of infiltrative masses and/or masses adjacent to large blood vessels. Intraoperative ultrasound is helpful in locating intraaxial neoplasms.

POSTOPERATIVE CARE AND ASSESSMENT

The patient is placed in a padded cage in an intensive care unit and is administered analgesics and antiseizure drugs as needed. They should be turned frequently. Postoperative vocalization is common in dogs after brain tumor removal, and dementia may be mistaken for pain, leading to overmedication in these patients. Oversedation and resultant prolonged recovery may predispose these dogs to atelectasis and subsequent pneumonia. Postoperative pneumonia is the most common and most severe postoperative complication of brain tumor removal in dogs and is better avoided than treated. PCV should be monitored frequently in cats after surgery.

PROGNOSIS

Most dogs and cats with brain tumors respond favorably to supportive therapy; however, such therapy is typically associated with very short survival times (approximately 1–4 months). In one study evaluating survival times in 51 dogs with primary brain tumors treated with supportive therapy alone, the median survival time after hospital discharge was 69 days; median survival time was significantly longer for dogs with supratentorial tumors (178 days), compared with those with infratentorial tumors (28 days).[11] For cats with surgical removal of meningiomas, the median survival time has previously been thought to be approximately 2 years; however, in a 2015 multicenter retrospective study of 121 cats with intracranial meningiomas that were surgically excised, the median survival time was 37 months.[12] The majority of deaths in the aforementioned study were due to causes unrelated to the meningioma. Regrowth of intracranial meningioma in cats usually occurs in the original tumor location. The success rate of reoperation of feline intracranial meningioma is similar to the reported success rate of first-time operation of these tumors; thus reoperation of a recurrent feline intracranial meningioma is a logical therapeutic option.

Survival rates reported for canine brain tumors with different modes of definitive therapy are quite variable. Part of this variability may be due to the inclusion of different tumor types and different variations of therapy within study populations. The tendency for these published rates to improve in general over time may reflect advancements in our ability to treat these tumors. In general, the prognosis for survival of dogs with intracranial neoplasia treated with surgery alone is poor. Canine meningiomas are generally more aggressive than feline meningiomas and tend to be more invasive. Canine meningiomas tend to recur within a year of surgery if adjunctive treatment is not pursued. Dogs with intracranial meningiomas treated with only hydroxyurea and prednisolone (i.e., no surgery or radiation therapy) have an average survival time of approximately 7 months, nearly twice the survival time of dogs treated with prednisolone alone. Survival times are longer for dogs with supratentorial versus infratentorial tumors. No information is available regarding survival times of dogs with intracranial gliomas treated by surgical removal. Dogs with gliomas treated with lomustine have survival times ranging from several months up to approximately 1 year. Megavoltage radiation therapy for meningiomas has generally been associated with average survival times between 1 and 3 years, although more recent studies (discussed later) suggest longer survival times. For gliomas, survival times reported for dogs treated with megavoltage radiation tend to average less than 1 year (approximately 10 months). Combined surgery and postoperative radiation therapy for canine meningiomas result in survival times of 1.5 to longer than 3 years. In one retrospective study of 31 dogs with intracranial meningioma treated via radiation (total dose of 45–54 Gy) alone (21 dogs, traditional fractionated protocol) or surgery and radiation (10 dogs), the overall median survival was 577 days (906 days when only dogs dying due to meningioma were considered); there was no significant difference in survival between the two groups.[13] In another retrospective study evaluating a stereotactic radiation delivery protocol (single median radiation dose of 15 Gy), 38 dogs with intracranial meningioma had a median survival time of 399 days (493 days when only dogs dying due to meningioma were considered).[14] Limited published data address the prognosis associated with the combination of surgery and oral chemotherapy for dogs with intracranial meningioma. These patients tend to survive for longer than a year, but not as long as those treated with postoperative radiation therapy or radiation therapy alone. In addition, small-breed dogs tend to have minimal postoperative complications (e.g., pneumonia) compared with large-breed dogs, and dogs with olfactory bulb meningiomas tend to have less postoperative morbidity and longer survival times than dogs with meningiomas located more caudally in the brain. With the exception of pituitary tumors and multilobular osteochondrosarcomas, the prognosis for secondary brain tumors in dogs and cats is generally considered to be poor.

COMPLICATIONS

The major postoperative complication for intracranial meningioma in dogs is pneumonia; this complication occurs in roughly 20% of patients. Postoperative pneumonia in these patients has an approximately 50% mortality rate. The most common postoperative complication in cats with intracranial meningioma is anemia. The reason for the anemia is unknown, but it virtually always responds to blood transfusion. It is important to monitor cats' PCVs every 4 to 6 hours for the first 24 hours after surgery and to transfuse if indicated (usually if PCV drops below 20%).

TRAUMATIC BRAIN INJURY

DEFINITION

Traumatic brain injury is brain damage due to externally applied trauma; it is mediated by direct (e.g., force of impact) and indirect (e.g., hemorrhage, edema, secondary inflammatory processes) factors.

GENERAL CONSIDERATIONS AND CLINICALLY RELEVANT PATHOPHYSIOLOGY

Severe traumatic brain injury in dogs and cats is an unfortunately frequent occurrence and is often associated with a guarded to poor prognosis, even with aggressive management. Much of the information regarding therapy for these patients is adapted from the human literature, although several veterinary-specific studies have been reported. In addition to the challenge of choosing and administering appropriate medical therapy for acute severe brain injury, a decision regarding whether or not surgical intervention is indicated for a particular patient is also essential. Although some differences in opinion have been expressed over what constitutes "appropriate" medical therapy for severe brain injury in veterinary and human patients, there is general agreement on most available treatment options. Less agreement has been noted among clinicians with respect to surgical intervention for severe brain injury, particularly in scenarios in which surgical therapy is used as a decompressive maneuver in the absence of intracranial hemorrhage.

Brain injury can be conceptually divided into primary and secondary injury. *Primary brain injury* occurs immediately following impact and initiates a number of biochemical processes, which result in *secondary brain injury*. Both primary and secondary brain injury contribute to increased ICP. Primary brain injury refers to the physical disruption of intracranial structures that occurs immediately at the time of the traumatic event. Such injury includes direct damage to brain parenchyma, such as contusions, lacerations, and diffuse axonal injury. Damage to blood vessels may result in intracranial hemorrhage and vasogenic edema. Skull fractures can contribute to continued trauma to the brain parenchyma and blood vessels, especially if they are unstable (Fig. 39.25). The extent of primary brain injury is a function of the force of impact. Acceleratory and deceleratory forces of both the impacting object(s) and the intracranial contents will affect overall tissue damage. Direct parenchymal damage associated with primary brain injury is generally beyond the control of the clinician. However, stabilization of skull fractures and evacuation of intracranial hemorrhage may decrease morbidity associated with primary injuries. In addition to continued hemorrhage and edema, damage caused by the primary brain injury activates a number of interrelated biochemical pathways that act in concert to perpetuate further brain tissue damage and subsequent increases in ICP. These processes constitute secondary brain injury.

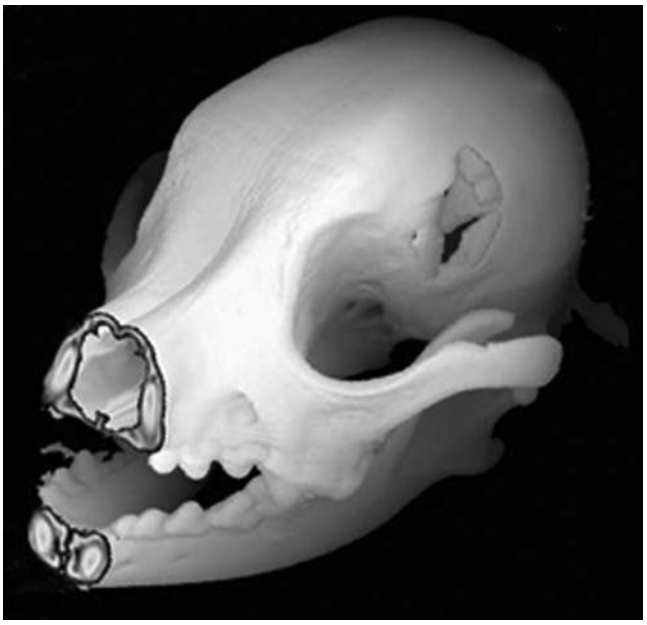

FIG. 39.25 Three-dimensional reconstructed computed tomography image of a dog with a depressed skull fracture. (Courtesy Dr. Charles Vite.)

Adenosine triphosphate depletion disrupts maintenance of cellular ionic homeostasis. Sudden, uncontrolled intracellular influx of sodium (Na^+) and calcium (Ca^{++}) occurs. Cellular swelling (cytotoxic edema) and depolarization result. Uncontrolled depolarization leads to the release of large amounts of glutamate, an excitatory neurotransmitter, into the extracellular environment. Glutamate causes further increases in intracellular Ca^{++} levels. Elevated Ca^{++} levels activate a number of tissue-damaging pathways, including the arachidonic acid cascade (phospholipase A_2 activation) and the xanthine oxidase (free radical producing) pathway. Iron (Fe^{++}) is a vital cofactor in the xanthine oxidase pathway, and free radical species generated via the Fenton reaction (e.g., hydroxyl and superoxide radicals) are preferentially damaging to cell membranes containing high levels of polyunsaturated fatty acids and cholesterol. Brain tissue is rich in both Fe^{++} and membranes with high levels of polyunsaturated fatty acids and cholesterol. Intraparenchymal hemorrhage also increases the amount of Fe^{++} available for perpetuation of oxidative damage. Free radical species are thus particularly damaging to neuronal membranes and probably play a major role in secondary brain injury. Their production is also induced by ischemia, arachidonic acid metabolites, catecholamine oxidation, and activated neutrophils. Other secondary autolytic processes induced after severe head trauma include the complement, kinin, and coagulation/fibrinolytic cascades. Elevated levels of nitric oxide and various cytokines (e.g., tumor necrosis factor, interleukins) also contribute to parenchymal injury in the damaged brain. Most of the mediators of tissue damage produced by these various reactions perpetuate their own continued production, as well as the production of other mediators. Maintenance of an ischemic environment perpetuates the previously mentioned processes and leads to the accumulation of lactic acid (via anaerobic glycolysis). Lactic acid

accumulation leads to further damage to brain tissue. Hypotension and hypoxemia, extracranial conditions that are common in the traumatized patient, can worsen brain ischemia, thereby enhancing the events responsible for secondary brain injury. The end result of these secondary processes is increased ICP. In contrast to primary brain injury, the clinician has some control over secondary brain injury.

DIAGNOSIS

Clinical Presentation

Signalment

Traumatic brain injury affects both dogs and cats, of any age and both sexes.

History

The history typically consists of a witnessed traumatic event, such as automobile trauma (hit by car), attack by a larger animal, fall from a height, or a projectile injury (e.g., gunshot).

Physical Examination Findings

Depending on the extent of trauma involved, physical examination findings may range from no apparent extracranial abnormalities and minor aberration of consciousness (see p. 1323) to severe multiorgan injury and coma.

Diagnostic Imaging

Imaging of the patient's head is often indicated, especially in those animals that fail to respond to aggressive medical therapy, or that deteriorate after responding to such therapy. Skull radiographs are unlikely to reveal clinically useful information in cases of severe head trauma but on occasion may reveal evidence of depressed fractures of the calvaria (Fig. 39.26). CT is the preferred modality for imaging the head in cases of severe brain injury. CT is preferred over MRI in head trauma cases for several reasons. CT images are obtained much more quickly than MR images (an important advantage in the critical patient scenario), patients may be more closely monitored with standard monitoring systems during CT than during MRI because of the large magnetic field required for MRI, and acute hemorrhage and bone are better visualized with CT than with MRI (Fig. 39.27). MRI can, however, provide additional prognostic information for head trauma patients. In one retrospective case series of dogs experiencing head trauma, MRI images were obtained within 48 hours of injury; in this investigation, it was found that T2 and fluid attenuation inversion recovery (or FLAIR) sequences provided the most clinically useful information, and that injuries involving the caudal fossa or both the caudal and rostral fossae had poorer outcomes.[15] In a retrospective study evaluating MRI results (MR images obtained within 2 weeks after trauma) in 50 dogs that had experienced severe traumatic brain injury, the MRI grade (based on factors such as lesion location, presence of midline shift, herniation) was negatively correlated with prognosis.[16]

FIG. 39.26 Lateral skull radiograph of a dog's head following severe traumatic brain injury, showing displaced skull fractures.

Laboratory Findings

Emergency bloodwork (e.g., PCV/total solids, Azostix, blood gas) should be performed, specifically focusing on evidence of trauma-related abnormalities (e.g., anemia). Admission hyperglycemia has been shown to be a poor prognostic indicator in dogs with severe traumatic brain injury.

DIFFERENTIAL DIAGNOSIS

In cases of traumatic brain injury in which the occurrence of trauma is obvious (historical and physical evidence of external trauma), there are no reasonable differential diagnoses.

MEDICAL MANAGEMENT

Most cases of traumatic brain injury in dogs and cats present with varying degrees of cardiovascular shock. Emergency management of the shock state takes precedence (ABCs of shock therapy) over focusing on the brain injury. Specific therapies for suspected brain swelling are discussed on pp. 1338 to 1342.

SURGICAL TREATMENT (Video 39.6)

Preoperative Management

Once normovolemia and appropriate oxygenation/ventilation have been established, the brain injury patient should be more

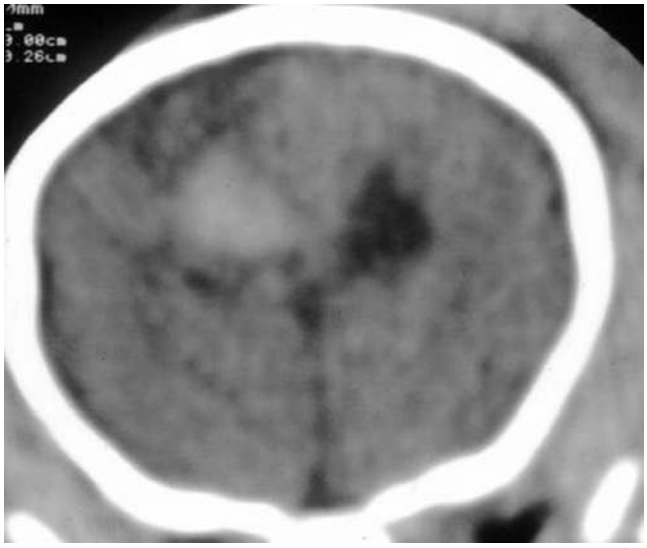

FIG. 39.27 Axial noncontrast computed tomography image of a dog that experienced traumatic brain injury, showing an area of intraparenchymal hemorrhage.

carefully assessed for other injuries to the nervous system (e.g., vertebral fractures/luxations), as well as to other body systems (i.e., lungs, abdominal organs, musculoskeletal system). A complete neurologic examination should be performed at this time. Specific medical therapy for brain injury should begin coincident with the secondary assessment (see pp. 1338–1342). Additional bloodwork, as well as radiographs, may be warranted.

Anesthesia

See p. 1340 for anesthetic management of the brain surgery patient.

Surgical Anatomy

See Chapter 38 and p. 1342 for surgical anatomy of the skull and brain.

Positioning

See descriptions of specific surgical approaches (pp. 1342–1344) for patient positioning.

SURGICAL TECHNIQUE

Surgical approaches used to decompress the brain, remove depressed skull fractures, and evacuate intracranial hemorrhage are typically the rostrotentorial or suboccipital approaches, depending on the location of the lesion(s). These approaches are described on pp. 1342 to 1344. When surgical decompression is required for brain swelling in brain injury cases, even if large pieces of skull need to be removed, the craniotomy defect should not be reconstructed. The brain should be allowed to expand in such cases, rather than be confined in a closed compartment. If the patient does well, the skull can be reconstructed at a later date, if indicated.

SUTURE MATERIALS AND SPECIAL INSTRUMENTS

Intraoperative ultrasound is a useful tool in brain injury cases in which an intraparenchymal hematoma needs to be located for surgical removal.

POSTOPERATIVE CARE AND ASSESSMENT

The patient is placed in a padded cage in an intensive care unit and is administered analgesics and antiseizure drugs as needed. Posttraumatic seizure activity is a concern in dogs experiencing traumatic brain injury, but does not appear to be a common phenomenon in cats.[17,18] Patients should be turned frequently.

PROGNOSIS

The prognosis for survival following severe traumatic brain injury remains guarded to poor overall. Nonetheless, many severely brain-injured dogs and cats make functional recoveries if provided enough time and appropriate postoperative nursing care.

Surgery of the Cervical Spine

GENERAL PRINCIPLES AND TECHNIQUES

DEFINITIONS

Weakness of all four limbs due to a cervical myelopathy is **tetraparesis.** When voluntary motor ability is lost to all four limbs, the term used is **tetraplegia. Hemiparesis** and **hemiplegia** are similar terms that refer to weakness of or inability to move the thoracic and pelvic limbs on one side of the body, respectively. The two most common surgical approaches to the cervical spinal cord are the **ventral slot procedure** (creation of a bony defect in the ventral aspect of an intervertebral space in addition to removing a section of the intervening disc) and dorsal laminectomy. The ventral slot procedure provides a small window to the ventral aspect of the spinal cord, but lateral access is limited by both the size of the defect and the large vertebral venous sinuses (internal vertebral venous plexus) on either side of the defect. **Dorsal laminectomy** provides a wide decompression and access to the entire dorsal surface of the cord. Further removal of the articular processes (facets) laterally **(facetectomy)** and/or the pedicles allows for exposure of the nerve roots/spinal nerve and lateral surface of the spinal cord, respectively. Removal of parts of the articular processes to enlarge the intervertebral foramen is called **foraminotomy**. Removal of the dorsal lamina on one side is often performed, usually combined with facetectomy/foraminotomy; this is called **dorsolateral hemilaminectomy. Hemilaminectomy** is the unilateral removal of the lateral surface of the vertebral arch, including the articular processes. Although this can be done in the cervical region, the term is used more commonly when discussing surgery of the thoracolumbar spine (see Chapter 41). **Fenestration** is the creation of a defect (window) in the annulus fibrosus to the level of the nucleus pulposus.

GENERAL CONSIDERATIONS

The range of neurologic dysfunction possible with cervical myelopathies is broad, in terms of both severity and character. Many patients present with severe neck pain as the primary or sole clinical sign of dysfunction. Neck pain is typically more severe with cranial cervical spinal cord lesions than with caudal lesions. Loss of motor function occurs with compressive cervical myelopathies but is less common than with thoracolumbar myelopathies, probably due to the larger volume of the vertebral canal in the cervical region compared with the thoracolumbar region. Ambulatory patients with caudal cervical myelopathy tend to have obvious pelvic limb weakness and ataxia, with less severe, sometimes even subtle, thoracic limb dysfunction. In many such cases, the thoracic limbs move with short, stilted steps, whereas the pelvic limbs display obvious ataxia. This odd gait is often referred to as a *two-engine gait* because of the disparate nature of the thoracic and pelvic limb movements. Patients with cranial cervical myelopathies typically have more obvious thoracic limb dysfunction. A phenomenon called *central cord syndrome* is sometimes appreciated in dogs and cats with caudal cervical spinal cord lesions that are confined to the central region of the cord. In this syndrome, the thoracic limbs display severe lower motor neuron (LMN) weakness, but the pelvic limbs are minimally affected or neurologically normal. This occurs because the centrally located lesion interferes with LMNs innervating the thoracic limbs, but it spares the more peripherally located white matter upper motor tracts that innervate the pelvic limb LMNs. Central cord syndrome is most commonly associated with intraaxial lesions like syringomyelia and neoplasia (see Chapter 38 and pp. 1353 and 1396).

Descending tracts from the medullary respiratory centers traverse the cervical spinal cord to innervate the phrenic nerve LMNs (C5–C7) and the LMNs of intercostal muscles in the thoracic spinal cord. Damage to these tracts can lead to respiratory compromise. Caudal cervical spinal cord lesions that spare innervation to the phrenic nerve LMNs (e.g., lesions caudal to the C5–C7 segments) but disrupt normal activation of intercostal LMNs can lead to the phenomenon of *abdominal breathing.* In this scenario, the diaphragm bears the sole burden of moving air through the lungs because of the denervated chest wall, and this motion causes the abdomen to visibly move back and forth during respiration. Tonic input to the sympathetic LMNs in the thoracolumbar spinal cord that maintain normal blood pressure is provided by neurons in the medulla (rostroventrolateral medulla). Because these medullary neurons send their processes through the cervical spinal cord, cervical myelopathies may be associated with severe hypotension.

Two major surgical approaches to the cervical spinal cord have been identified: ventral and dorsal. A lateral approach to the cervical cord is rarely performed and is not discussed in this text. The ventral approach is technically less demanding than the dorsal approach, and considerably more bone is available for implants ventrally versus dorsally when vertebral stabilization is required. Exposure of the vertebral canal and the spinal cord is very limited with a ventral approach, and the likelihood of severe venous sinus hemorrhage is much greater than with a dorsal approach. The dorsal approach allows for wide decompression and access to dorsal and lateral aspects of the cervical spinal cord. This procedure is technically more difficult than the ventral approach, and patients with dorsal cervical laminectomies tend to have longer recuperative periods than those who undergo ventral slot procedures. The dorsal spinous processes in the cervical region are short (and are typically removed during

ABSTRACT

Disorders of the cervical spine are common in small animal practice and can be challenging to treat. Type I disk ruptures are frequently encountered and can be successfully managed via both ventral (ventral slot) and dorsal (dorsal laminectomy, facetectomy) approaches. In addition to disk disease, other fairly frequently encountered cervical spinal cord problems include congenital abnormalities (e.g., atlantoaxial instability), spondylomyelopathy ("wobbler syndrome"), neoplasia and traumatic fracture/luxation.

Other surgical techniques for dealing with cervical spine abnormalities include implant placement for unstable segments (e.g., atlantoaxial instability, trauma).

spondylomyelopathy

decompression), and the articular processes afford a small amount of bone stock for implant placement. In some instances, both a ventral and a dorsal approach are needed to accomplish the goals of surgery. Dorsally directed (interarcuate) branches of the internal vertebral venous plexuses (venous sinuses) at the articular process levels may bleed during the dorsal approach or during facetectomy/foraminotomy. However, this hemorrhage is easier to control because of the visualization afforded by the dorsal approach. Venous sinus hemorrhage that is severe and difficult to visually pinpoint is addressed by placing Gelfoam over the site of hemorrhage with slight pressure, using Bishop-Harmon forceps. Suction is used to evacuate blood around the site of hemorrhage. If the hemorrhage is less severe and can be localized to a small area, Surgicel can be used over the hemorrhage site. This is less obtrusive and will allow the surgeon to continue working in areas that are not bleeding. This method of hemorrhage control is particularly useful with approaches that are smaller (i.e., ventral slot approach).

Preoperative Management

Specifics of preoperative management depend largely on the disease process. In cases of suspected or known vertebral instability, the patient needs to be kept as still as possible and may need some external support (e.g., neck brace, secured to a board or other rigid surface). It is extremely important to emphasize the dangers of neck manipulation in such animals to everyone who may be handling the patient. Once the dog or cat is anesthetized, voluntary contraction of the cervical musculature will no longer be an available protective mechanism for that patient. If radiographs are obtained, overzealous neck flexion in an effort to demonstrate atlantoaxial (AA) instability may prove fatal. With increased availability of multislice computed tomography (CT) scanners and magnetic resonance imaging (MRI) units, safe and more accurate imaging methods are available for patients with cervical spine disorders.

A hallmark of many cervical myelopathies is neck pain, which is often severe. Oral prednisolone (0.5 mg/kg every 12 hours) is often effective in relieving pain in some cervical myelopathies. In chronic compressive myelopathies, this dose of prednisolone will also likely improve clinical signs through its effect on spinal cord edema. High doses of glucocorticoids should not be administered as an emergency or preemptive presurgical therapy for spinal cord injury. The "high-dose" methylprednisolone protocol has been ineffective for spinal cord injury and can have deleterious consequences (e.g., gastrointestinal ulceration/perforation). Polyethylene glycol (PEG) has been used for spinal trauma in dogs due to its ability (in experimental models) to fuse damaged cell membranes. However, a 2016 double-blinded, placebo-controlled study in dogs with acute severe spinal cord injury associated with thoracolumbar disc extrusions concluded that both PEG and methylprednisolone sodium succinate had no beneficial clinical effect.[1] Injectable opioid drugs (e.g., fentanyl) are usually effective analgesics in hospitalized patients (see Chapter 13). Gabapentin and pregabalin are oral calcium channel blocking drugs used as both antiseizure agents and antinociceptive agents (see Table 39.1 and pp. 149 and 1140). Pregabalin is the "next generation" of gabapentin. Although gabapentin is often an effective pain-relieving oral drug, pregabalin appears to be superior.

Anesthetic Considerations

Specific anesthetic concerns associated with cervical spinal cord surgery are hypotension, blood loss, cardiac arrhythmias, ventilatory compromise, and pain management. Because of the potential for venous sinus blood loss, blood should be available for transfusion (see Chapter 4). Severe hypotension, whether due to blood loss, lack of sympathetic tone, or both, can be treated with fluid support and/or positive inotropic drugs (see Table 4.5 and Box 19.6). Bradycardia may occur with vagal nerve stimulation during the ventral approach and can be treated with anticholinergic drugs (atropine or glycopyrrolate; see Chapter 12). Mechanical ventilation may be necessary both during and after surgery, depending on the severity of the myelopathy.

Taping the animal across the chest to maintain positioning at surgery can cause severe respiratory compromise if the tape is applied too tightly; it is best to avoid this practice and to rely on other methods (e.g., V trough, towels, vacuum apparatus) to maintain positioning for surgery. Excessive neck extension should be avoided during positioning because this may exacerbate compression in some situations (e.g., disc protrusions, caudal cervical spondylomyelopathy [CCSM]). The endotracheal tube should extend beyond the thoracic inlet during ventral approaches to the cervical spine so that the trachea is not damaged during retraction at surgery.

Anesthetic protocols vary but are similar to those used for fracture repair surgery (see Tables 32.1 and 32.2). Premedication with an opioid drug is often performed, as many of the cervical myelopathies are characterized by severe neck pain. If myelography is to be performed before surgery, the potential for postmyelographic seizures exists, especially in larger dogs. Antiseizure drugs are discussed in Chapter 39 (see Table 39.1).

ANTIBIOTICS

In dogs and cats undergoing surgery of the cervical spine, intravenous antibiotics (e.g., cefazolin, 22 mg/kg) should be administered perioperatively (30 minutes before the surgical incision is made and every 90–120 minutes during surgery).

SURGICAL ANATOMY

Seven cervical vertebrae are present, each of which has a body, laminae, pedicles, transverse processes, and articular processes. All but the first cervical vertebra (C1) have a dorsal spinous process. From C3 to C7, these processes slope in a cranial direction and increase in size from cranial to caudal. No intervertebral disc is found between the first and second cervical vertebrae. Distinctive features of the first (C1), second (C2), and sixth (C6) cervical vertebrae provide important landmarks for the surgeon; similarly, the large dorsal spinous process of the first thoracic vertebra (T1) is a distinct surgical landmark (Fig. 40.1). The first cervical vertebra (C1), the atlas, has a shortened body (the ventral arch); wide, shelf-like transverse processes (wings); and modified articular processes. The ventral tubercle of C1 feels like a distinctive "spike" when palpated during a ventral approach (Fig. 40.2), compared with the smooth "bump" of the ventral aspect of the intervertebral disc spaces. The dorsal spinous process of C2 (the axis) is a distinctive bladelike structure, the caudal aspect of which is very thick and partially overhangs the dorsal aspect of C3. The dorsal spinous process of C3 is extremely small and is sometimes nonapparent, especially in miniature and toy dog breeds. The dorsal lamina of C3 in these small breeds may be very short as well. It is important not to confuse C4 with C3 while performing a dorsal approach in the cranial cervical spine, especially in small dogs and cats. The articulation between C1

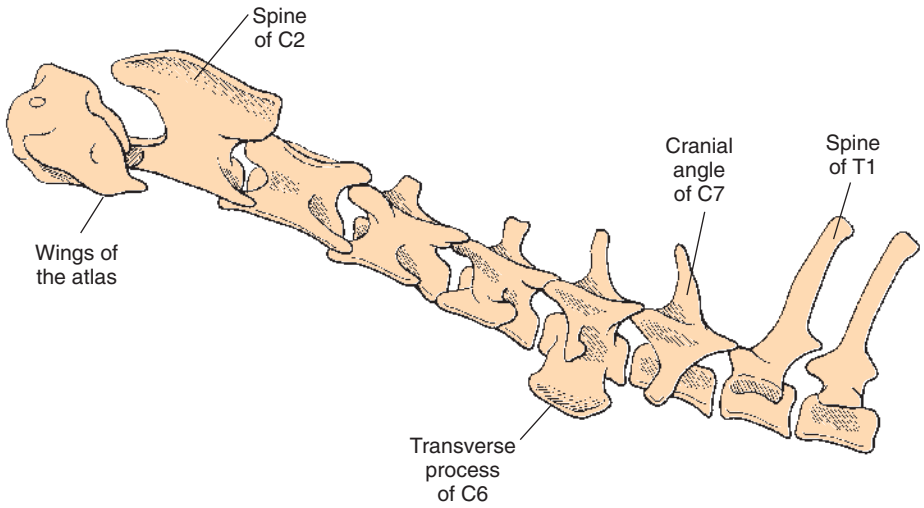

FIG. 40.1 Distinguishing anatomic landmarks of the cervical spine.

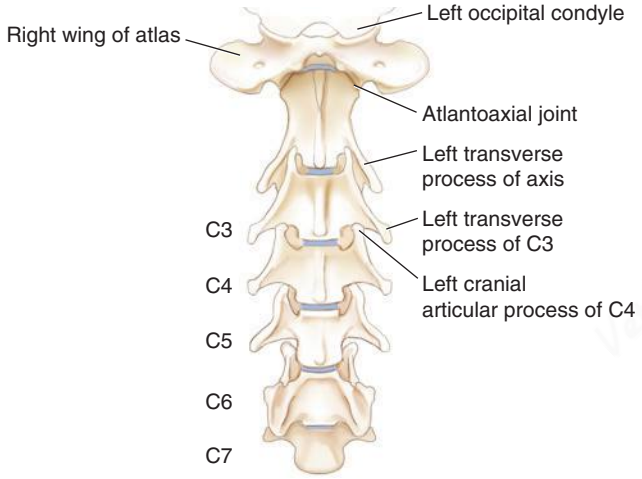

FIG. 40.2 Illustration of the ventral aspect of the cervical spine in the dog.

and C2 involves a cranial projection of the body of C2 (the dens) that rests on and is attached to (via several ligaments) the dorsal aspect of the C1 ventral arch (Fig. 40.3). The transverse processes of C6 are very prominent ventral structures that are easily palpated during the ventral approach. The dorsal aspect of the first rib as it articulates with T1 can also be palpated during the ventral approach; however, the surgeon must be cautious not to rupture the thin cupula pleura during palpation of this structure.

In addition to the venous sinuses on the floor of the vertebral canal, a vertebral artery is present on each side of the cervical spine. This large artery traverses the transverse foramina from C6 through C1 and is located ventral to the level of the articular processes from C2 through C6. The vertebral artery is usually not encountered during standard approaches to the cervical spine; disruption of this vessel during surgery can lead to rapid and extensive hemorrhage. Eight paired cervical spinal nerves are present. The paired first cervical spinal nerves exit from the lateral vertebral foramina of C1. The C2 through C7 spinal nerves exit through the intervertebral foramina cranial to the vertebra of the same number as the specific nerve (i.e., the C2 spinal nerve exits at the C–C2 foramen). The C8 spinal nerve exits the foramen formed by the C7 and T1 vertebrae. The nuchal ligament extends from the T1 dorsal spinous process to the caudal aspect of the C2 dorsal spinous process (Fig. 40.4). This structure is helpful during the dorsal approach both in verifying anatomic location and as a tool for remaining on midline (the nuchal ligament is a paired structure that can be split on the midline).

STANDARD SURGICAL APPROACHES TO THE CERVICAL SPINE

The main indication for performing a ventral approach to the cervical spine is to create a ventral slot for removal of ventrally located disc material. This approach is also used to stabilize cervical vertebral segments by placing implants in the vertebral bodies (e.g., AA instability, CCSM, traumatic fracture/luxation). When performing the ventral slot procedure, especially in small dog breeds, visualization of the limited surgical field can be challenging. The use of visualization aids, such as binocular magnification loupes or a high-definition video telescope system, can be of great benefit.[2] The dorsal approach is used to decompress the spinal cord and to remove dorsally or laterally situated compressive lesions (e.g., lateralized disc, hypertrophied yellow ligament, spinal tumors). The dorsal approach can be extended laterally by removing articular joint capsules (facets) and adjacent pedicles to improve access to the lateral vertebral canal.

Ventral Approach to the Cervical Spine

Shave the skin and aseptically prepare the area from approximately the midmandible level cranially to several centimeters past the manubrium caudally. The length of the surgical incision depends on the specific area to be operated. *Position the patient in dorsal recumbency with the head and neck in mild extension (Fig. 40.5). Secure the thoracic limbs by pulling them caudally and against the patient's trunk. Use a V trough or towels to position the neck area. Place a towel beneath the neck to facilitate extension. Secure the head with tape placed over the upper canine teeth.*

Assuming that the entire cervical region is to be exposed, make a ventral midline incision from the level of the larynx cranially to the level of the manubrium caudally (Fig. 40.6). Divide the

sternocephalicus muscles to the level of the manubrium with Metzenbaum scissors or unipolar cautery if access to the caudal cervical spine is required. Divide the paired sternohyoideus muscles on midline (median raphe) with Metzenbaum scissors (Fig. 40.7). During this division, use bipolar cautery to address branches of the caudal thyroid veins that are in the dissection plane. Digitally separate the deep neck fascia, and visually identify then retract the trachea, esophagus, and left carotid sheath to the left and the right carotid sheath to the right. Once these structures are retracted, visualize the longus colli musculature (Fig. 40.8) and perforate the overlying fascial covering with Metzenbaum scissors; remove this fascia digitally using anatomic reference points discussed previously to identify the intervertebral space of interest. Bluntly separate the longus colli musculature on midline at the cranial and caudal aspects of the disc space (for spaces C2-C3 and caudally), using a straight Kelly or Mosquito forceps, while exposing the tendons of insertion of the longus colli muscles on the ventral tubercles of the vertebrae. Dissect these tendon insertions from the tubercles using Freer elevators (small dogs and cats), or cut them with Mayo scissors (large dogs). Continue the dissection of the longus colli musculature off the ventral aspect of the vertebral bodies to be exposed using Freer elevators or narrow Army-Navy osteotomes (large dogs). Once this dissection is complete, place Gelpi retractors in the cranial and caudal aspects of the area of interest, with the tips of the retractors beneath the longus colli musculature (Fig. 40.9). Control hemorrhage during this approach using bipolar cautery. When approaching the

C–C2 intervertebral space, transect the belly of the sternothyroideus muscle to facilitate exposure of this joint space. Using a No. 11 blade, incise the small muscle (rectus capitis ventralis) over the ventral surface of C1 and reflect it laterally with Freer elevators to expose the C1 ventral arch. To perform the ventral slot procedure (Videos 40.1 and 40.2), first fenestrate the disc of interest by resecting a rectangular section of the ventral annulus, and remove this piece of annulus with Lempert rongeurs, exposing the nucleus pulposus (Fig. 40.10A–B). Remove the ventral tubercle from the caudal aspect of the cervical vertebra forming the cranial aspect of the intended

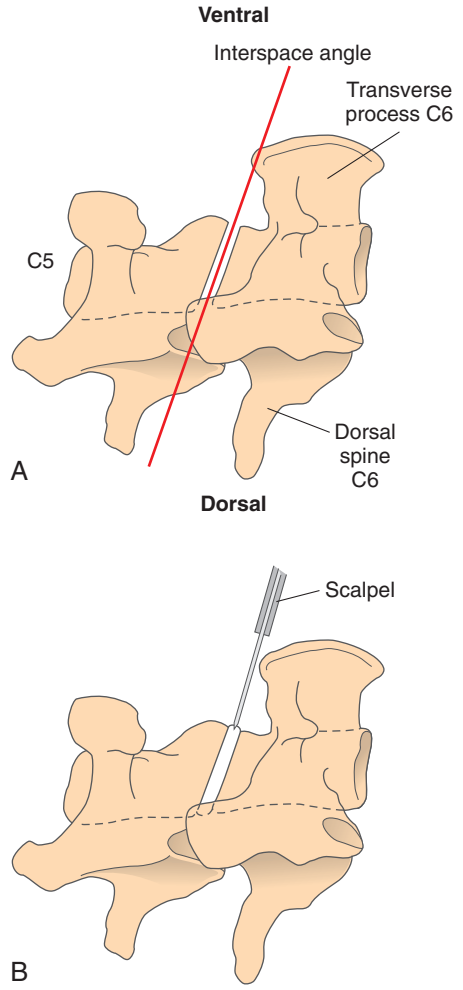

FIG. 40.10 (A) Note the slight cranial-to-caudal angle of the cervical vertebral interspaces. (B) To excise the ventral annulus, the scalpel blade should be inserted at this cranial-to-caudal angle.

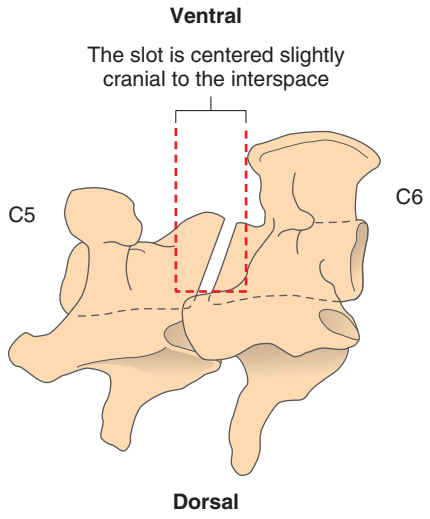

FIG. 40.11 Cranial and caudal extent of the ventral slot defect based on the caudal-to-cranial angle of the intervertebral space.

slot. Center the slot toward the vertebral body cranial to the disc because of the caudal-to-cranial direction of the intervertebral space from ventral to dorsal (Fig. 40.11). Do not exceed one-third the width or length of the vertebral bodies when creating the ventral slot. Using a high-speed air drill with a 4- to 5-mm burr, remove the outer cortical and inner cancellous bone layers, noting the spongy red nature of the cancellous layer during drilling. Stay on midline throughout creation of the slot to minimize the chance of rupturing the venous sinuses when entering the vertebral canal (Fig. 40.12A–B). If the cancellous bone bleeding is enough to interfere with visualization, use bone wax to stop the hemorrhage. When the bone again turns white, the inner cortical layer has been reached. *Use a smaller burr (e.g., 2–3 mm) to remove this final bone layer. Be cautious to avoid abruptly breaking through this layer.* The inner cortical bone takes on a flaky appearance, much like filo dough, just before the vertebral canal is penetrated. *Use a probe (e.g., Gross ear hook and spoon) to get under the dorsal annulus, and incise this last layer of the disc with a No. 11 blade. The adjacent periosteal layer is often incised concurrently if the inner cortical layer is thin enough. Once the inner cortical bone layer is thin enough, or if there is a window into the vertebral canal, use a 4-0 bone curette to enlarge the slot defect. In small-breed dogs, a distinct dorsal longitudinal ligament may not be apparent (may be removed with the periosteal layer); in larger dogs, this dull white fibrous structure may be distinct (Fig. 40.13). Carefully incise the dorsal longitudinal ligament with a No. 11 blade, if necessary, to gain entry into the vertebral canal (Fig. 40.14).* Fibrous (annular) material at the sides of the slot defect will have a frayed appearance, like irregularly cut rope. Calcified nucleus pulposus will appear white and granular, like miniaturized cottage cheese. The dura mater will be smooth and glistening and may be a bright white color or bluish-white (bruising from disc rupture). *Remove disc material within the vertebral canal using a probe and Bishop-Harmon forceps so that the dura is visualized. Use the probe to "sweep" underneath the edges of the slot to remove as much disc material as possible.* During disc removal and sweeping around the slot defect, it is common to lacerate a venous sinus. *Control venous sinus hemorrhage as previously described. After copious lavage of the surgical site, close the longus colli muscles with simple interrupted sutures. If a caudal exposure was performed, reappose the sternocephalicus muscles with simple interrupted sutures.* The sternothyroideus muscle does not need to be reattached if this muscle was severed during C1–C2 exposure. Subcutaneous and skin closure is routine.

Dorsal Approach to the Cervical Spine

The specific dorsal approach chosen differs depending on what part of the dorsal cervical spine is operated. For all variations of the dorsal approach, it is extremely important to stay on midline and to divide paired muscular and tendinous structures as much as possible; doing so will minimize hemorrhage and postoperative discomfort. Carefully identify dorsal cervical musculature layer by layer, using Gelpi retractors in the cranial and caudal limits of the surgical exposure as successive layers are reached.

For all of the dorsal approaches, place the patient in sternal recumbency with the neck gently flexed in a neutral position (Fig. 40.15). When the approach to the cranial cervical spinal cord is combined with suboccipital craniotomy (see p. 1344), flex the neck more acutely. The lateral limits of the shaved and aseptically prepared skin area extend to the middle third to half of the dorsal-ventral neck region on each side. The cranial limit of this

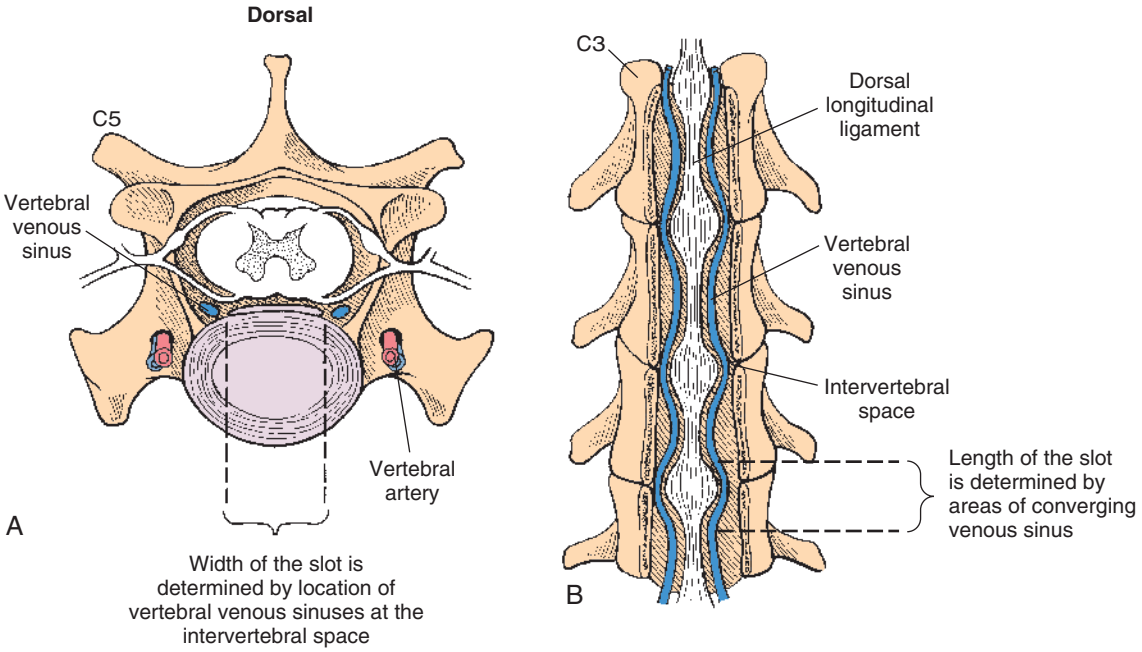

FIG. 40.12 (A) Cross section of the cervical spine showing vertebral venous sinus and vertebral artery relative to the intervertebral disc and spinal cord; the width of the slot is determined by this relationship. (B) Laminectomized cervical spine showing the shape of the vertebral venous sinus and the dorsal longitudinal ligament relative to the intervertebral spaces; the length of the slot is determined by this relationship.

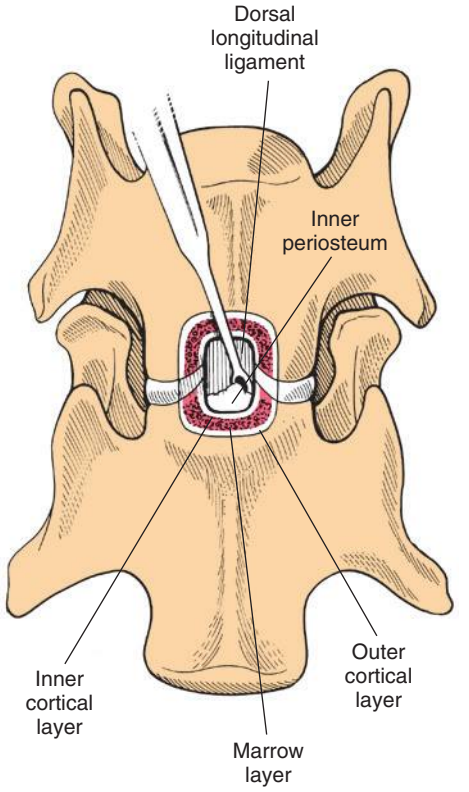

FIG. 40.13 The proper depth of the ventral slot defect is determined by identifying outer cortical, medullary, and inner cortical layers of bone; once the inner cortical layer is reached, use a 3-0 or 4-0 curette to expose the dorsal longitudinal ligament.

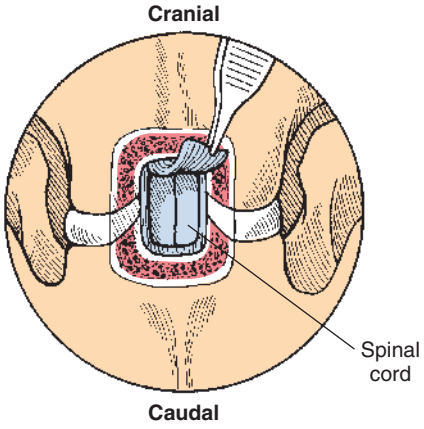

FIG. 40.14 Decompression is complete when the spinal cord is visualized.

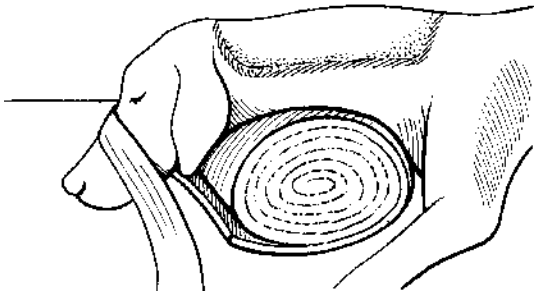

FIG. 40.15 To position an animal for cranial cervical laminectomy, gently flex and support the neck.

area for cranial cervical and midcervical approaches is the external occipital protuberance. For midcervical and caudal cervical approaches, the caudal limit of the surgical site is approximately at the level of the dorsal spinous process of T2 or T3. The cranial limit of the surgical site for caudal cervical approaches is approximately at the level of C3.

For a cranial cervical approach, incise the skin on the dorsal midline from the external occipital protuberance to the midcervical region (C4 or C5 dorsal spinous process level). Locate the midline fibrous raphe of the superficial cervical musculature (Fig. 40.16). Incise this connective tissue with a No. 11 blade, and carefully continue the midline incision cranially and caudally with Metzenbaum or Mayo scissors, controlling hemorrhage with monopolar and/or bipolar cautery. Reflect and retract the superficial cervical musculature to expose the paired splenius muscles. Divide these muscle bellies, as well as those of the underlying biventer cervicis muscles, to expose the next layer of paired muscles: the rectus capitis dorsalis muscle cranially and the spinalis cervicis muscle caudally (Fig. 40.17). Identify the nuchal ligament extending caudally from the caudal aspect of C2 at this level. Using a combination of sharp and blunt dissection, elevate the rectus capitis dorsalis muscle off the C2 dorsal spine. Sharply transect the attachment of the nuchal ligament off the caudal aspect of C2, and divide the muscle bellies of the spinalis cervicis muscles over C3. Using a Freer elevator, bluntly elevate these muscles laterally, exposing the dorsal lamina of C3 (Fig. 40.18). The approach for access to the C1–C2 cervical region is discussed in Chapter 39 (suboccipital

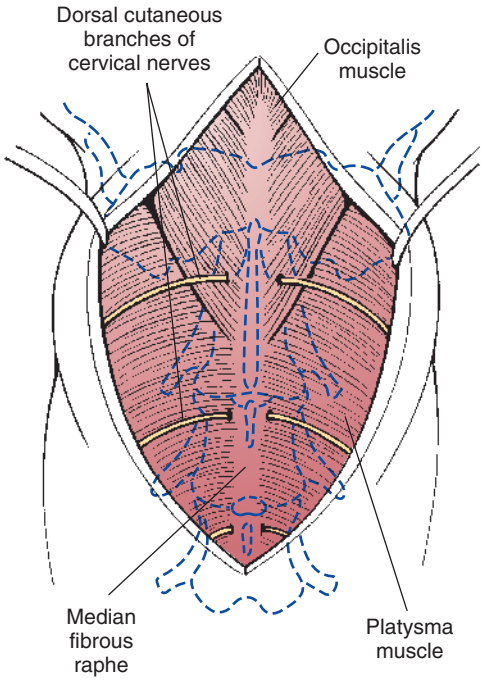

FIG. 40.16 During cervical laminectomy, dissect on the midline of the superficial cervical musculature to expose the median raphe and cutaneous nerves.

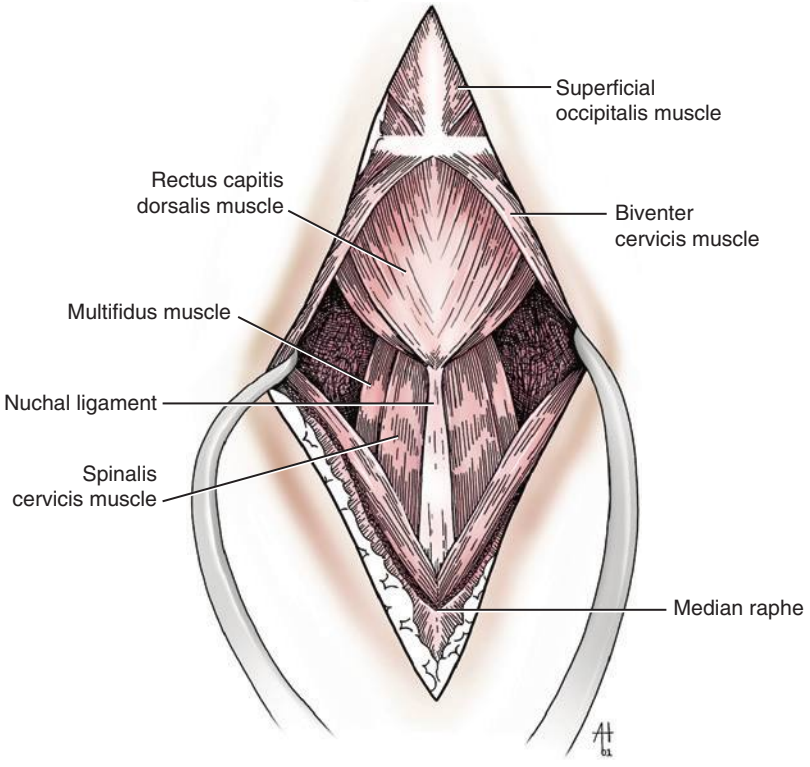

FIG. 40.17 Separation of the median raphe exposing superficial occipitalis muscle, biventer cervicis muscle, rectus capitis dorsalis muscle, spinalis cervicis muscle, multifidus muscle, and nuchal ligament.

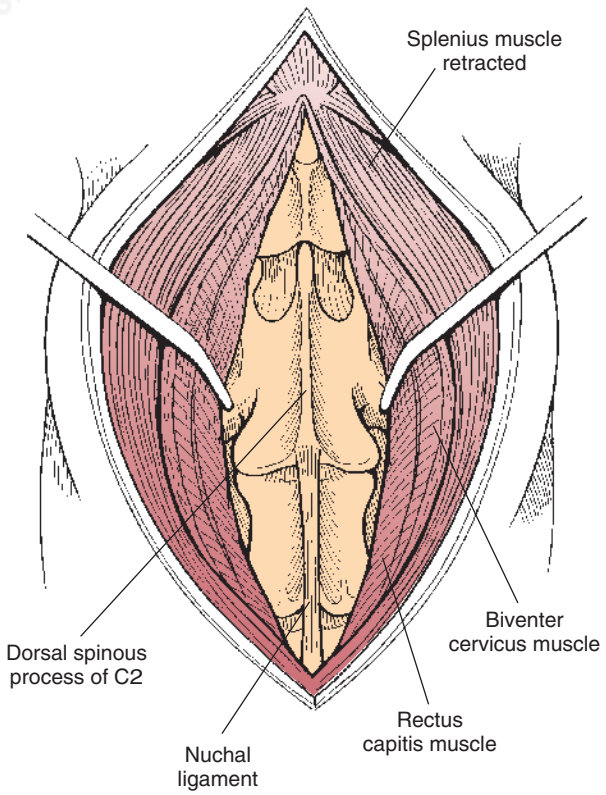

FIG. 40.18 During cranial cervical laminectomy, elevate muscle from the spinous processes and the laminae of C1–C2.

craniotomy) (see p. 1344). The initial dorsal approach to the midcervical and caudal cervical regions is similar to that for the cranial cervical approach, with incision of the median raphe of the superficial cervical muscles and retraction of these muscles laterally. *To access the dorsal laminae of C4 through C7, divide the nuchal ligament on midline and retract the paired components laterally with Gelpi retractors, exposing the underlying epaxial musculature. Using Mayo scissors, circumferentially cut the tendinous attachments of the spinalis cervicis and multifidus muscles to the dorsal spinous processes, then bluntly elevate these muscles off the dorsal lamina with Freer elevators (small dogs and cats) or Army-Navy osteotomes (large and giant dog breeds). Remove attachments of the multifidus muscles to the articular processes using a combination of periosteal elevators and bipolar cautery (Fig. 40.19A–B). Remove the dorsal spinous processes of the desired surgery site with rongeurs or bone cutters. Use a high-speed air drill to create the laminectomy defect.*

The defect should extend the length of the vertebrae of interest and should extend laterally to the level of the articular processes (Fig. 40.20). In medium- to giant-breed dogs, the bone will change in color and character as in the ventral slot procedure (i.e., outer cortical, inner cancellous, inner cortical). In cats and small-breed dogs, the dorsal lamina in the cervical region is often very thin, and an obvious inner cancellous bone layer may not be apparent.

HEALING OF THE SPINAL CORD

Three basic categories of change occur after acute injury to the spinal cord: (1) direct morphologic distortion of neuronal tissue,

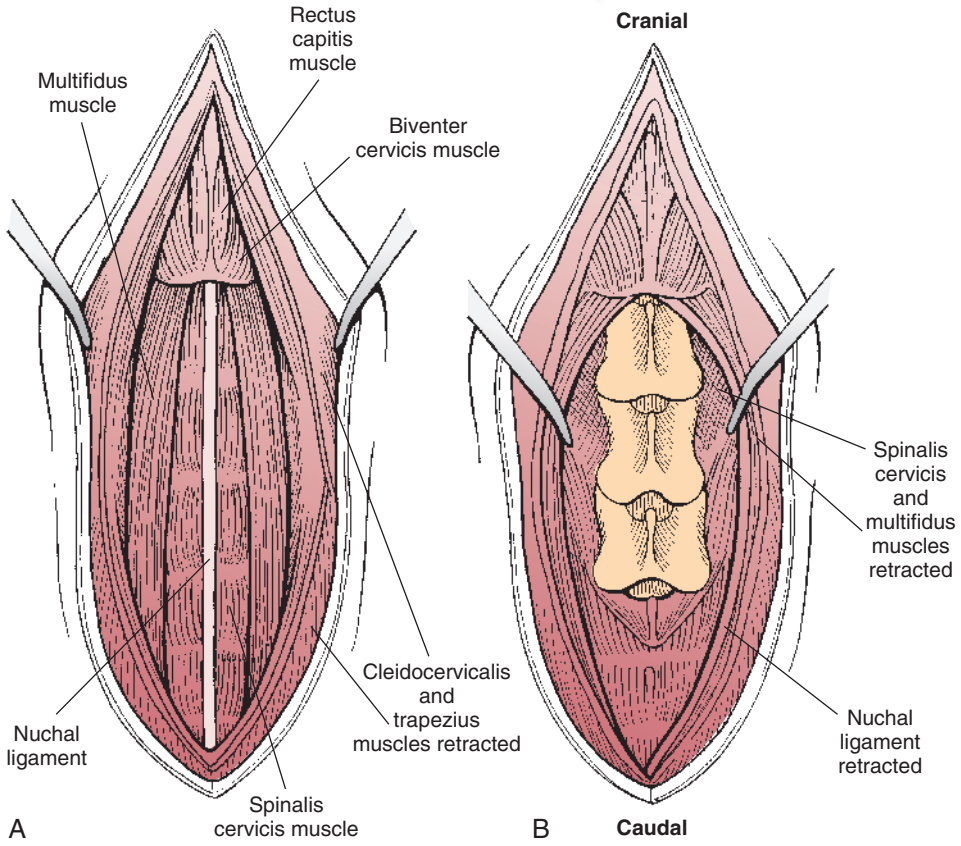

FIG. 40.19 (A) Identify the median fibrous raphe and the nuchal ligament during dorsal midcervical laminectomy and use them as landmarks. (B) Elevate the cervical musculature from the dorsal spinous processes and laminae of C3, C4, and C5.

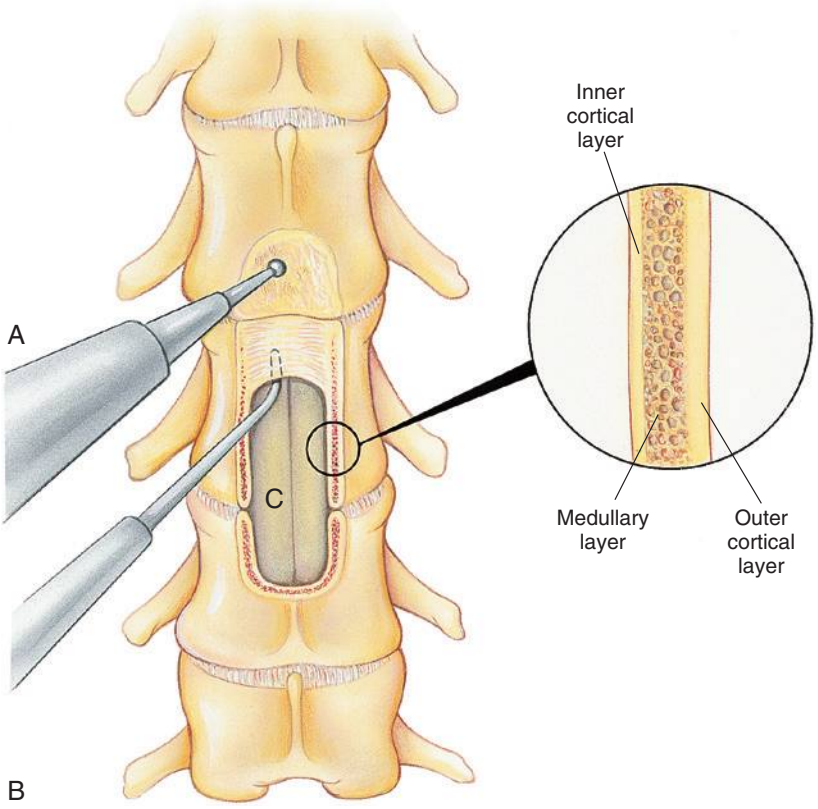

FIG. 40.20 (A) Use a pneumatic bone drill to expose outer cortical, medullary, and inner cortical layers of laminar bone. (B) Elevate the periosteum with a dental spatula to gain exposure to the vertebral canal. (C) Expose the spinal cord and nerve roots.

as well as severe axonal injury; (2) vascular changes; and (3) biochemical and metabolic changes. Controversy exists regarding the relative importance of these closely related categories in causing functional deficits. Direct morphologic damage to spinal cord tissue (e.g., laceration, compression, stretching) resulting in axonal interruption is believed to be irreversible and untreatable because central axons do not regenerate sufficiently to restore function.

In the case of reversible spinal cord injury, a characteristic series of events occurs during the repair process. Approximately 2 days after injury, a heterogeneous population of small cells (most likely of hematogenous origin), including polymorphonuclear, lymphocyte, macrophage, and plasma cells, invade the traumatized tissue. This is essentially an inflammatory response. Within 7 to 20 days, fibroblasts make their appearance and begin laying down scar tissue. A concurrent glial reaction consisting of astrocyte proliferation and expansion of processes occurs. Depending on the extent of spinal cord injury, moderate to extensive fibrosis, nerve fiber degeneration, and multifocal malacia may be seen. Axons that have been severed, compressed, or stretched start to regrow until they reach the edges of the scar mass. Regeneration of spinal cord axons sufficient enough to restore function has not been achieved; however, if enough axons remain intact, return to clinically acceptable motor function can be expected.

SUTURE MATERIALS AND SPECIAL INSTRUMENTS

Neurosurgical instrumentation required for cervical spinal surgery is similar to that discussed for brain surgery (p. 1345). For dorsal laminectomies in the cervical region, deep right-angled Gelpi retractors are helpful in providing exposure. Angled burr guards are also needed to create a shelf under a ventral slot for anchoring polymethylmethacrylate (PMMA) in the PMMA plug technique for CCSM (see p. 1384).

POSTOPERATIVE CARE AND ASSESSMENT

Critical care observation for the first 24 hours postoperatively includes monitoring respiration, administering analgesics, and observing for gastric dilatation-volvulus (particularly in large- and giant-breed dogs) and seizure activity (particularly if the patient had preoperative myelography). Blood gas analysis is warranted in animals with ventilatory compromise. Postoperative analgesia is provided by low doses of opioids, thus reducing their respiratory depressant effects (see Table 13.2). Fluids should be administered at maintenance rates and the patient turned every 2 hours until sternal. Glucocorticoid administration is generally discontinued postoperatively. If neurologic status deteriorates after surgery, glucocorticoids may be given until the cause is determined or corrected. Ambulatory patients may be discharged 3 to 5 days after surgery and should be confined for 2 to 4 weeks. They should walk on a harness for 4 to 8 weeks. Nonambulatory patients are treated with frequent hydrotherapy, physiotherapy, an elevated padded cage rack, frequent turning, and bladder expression three to four times a day. They should be kept clean and dry to prevent decubital ulcers. Avoid indwelling urinary catheters because they are a frequent cause of urinary tract infection. A supporting cart helps nurse patients to an ambulatory status. Advantages of a

cart include unhindered eating, drinking, micturition, and defecation. Additionally, animals with motor function are encouraged to ambulate, and an erect position facilitates physiotherapy. Nonambulatory patients may be discharged when owners are able to care for them. Neurologic examinations should be performed at 1, 2, 3, 6, 9, and 12 months postoperatively, or until improvement has ceased.

COMPLICATIONS

Complications associated with cervical spinal surgery are uncommon and include excessive hemorrhage from venous sinus laceration (may require blood transfusion), worsening of neurologic signs after surgery (usually transient, but permanent injury is a risk), postoperative infection, and seroma formation. Less common is vertebral instability and luxation from performing too wide a ventral slot. Recumbent patients are prone to urinary tract infection, particularly if they are receiving glucocorticoids.

SPECIAL AGE CONSIDERATIONS

Softer cortical bone of lamina, pedicles, and vertebral bodies of young animals requires less aggressive drilling and rongeuring than the denser, more compact bone of older dogs.

SPECIFIC DISEASES

CERVICAL DISC DISEASE

DEFINITIONS

Cervical disc disease refers to degeneration of the nucleus pulposus (**Hansen type I,** or **type I** degeneration) or annulus fibrosus (**Hansen type II,** or **type II** degeneration) components of cervical discs and the clinical consequences of such degeneration. Type I degeneration is also called *chondroid degeneration,* whereas type II degeneration is called *fibroid degeneration.* A third, less commonly encountered type of disc disease, hydrated nucleus pulposus extrusion (**HNPE**), has also been described (previously termed *discal cyst*); this is typically an acute-onset extrusion of hydrated nucleus pulposus material in the cervical region. HPNE likely represents a clinical variant of type I disc degeneration. There is evidence that there is some degree of nuclear degeneration in HNPE cases, suggesting that these are extrusions of an "almost healthy" nucleus pulposus.[3–9] **Radiculopathy** means pathology of the nerve roots and is often manifested as pain due to compression by disc material; when a radiculopathy leads to lameness or holding up a thoracic limb because of suspected irritation/pain, this is called a **root signature.**

GENERAL CONSIDERATIONS AND CLINICALLY RELEVANT PATHOPHYSIOLOGY

Degenerative disc disease is a common problem in dogs but a relatively infrequent clinical disorder in cats. Two commonly encountered types of disc degeneration (type I and type II) typically cause two distinct types of disc disease (Figs. 40.21 and 40.22). In *chondroid (type I) degeneration*, the normally gelatinous nucleus pulposus loses water-binding capacity, undergoes degradation of the glycosaminoglycan components, and often becomes calcified. The dorsal annulus often weakens, and the abnormal nucleus pulposus contents extrude through the weakened annulus into the vertebral canal. The severity of spinal cord damage caused by type I disc extrusion is believed to be related to the rate of extrusion (force of impact or concussion), the duration of compression, and the amount of disc material extruded. *Fibroid (type II) degeneration* involves progressive thickening of the dorsal annulus fibrosus, which protrudes dorsally into the vertebral canal over an extended period of time. Type I and type II degeneration can occur concurrently; these terms do not impose limitations on the pathologic behavior of abnormal discs. The phenomenon of "acute-on-chronic" disc rupture occasionally occurs, in which a dog with chronic signs of probable type II protrusion worsens rapidly owing to sudden extrusion of nucleus pulposus into the vertebral canal (type I extrusion). As previously mentioned, HNPE likely represents a variant of type I disc degeneration. The clinical scenario with HNPE is typically consistent with an acute compressive myelopathy. The compressive material in this type of extrusion is hydrated ("healthy") nucleus pulposus; it is thought that these extrusions arise from discs that are in an early stage of degeneration.[3–9]

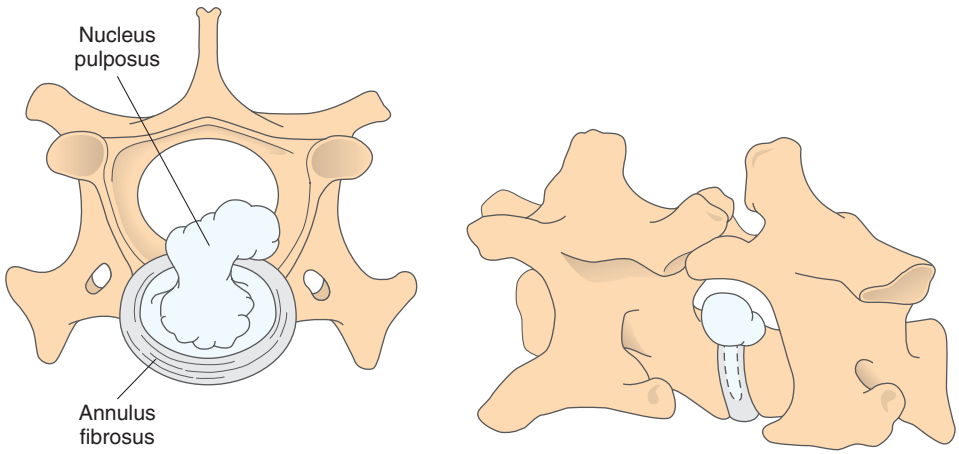

FIG. 40.21 Hansen type I disc degeneration is characterized by an acute massive extrusion of degenerate nuclear material in the vertebral canal.

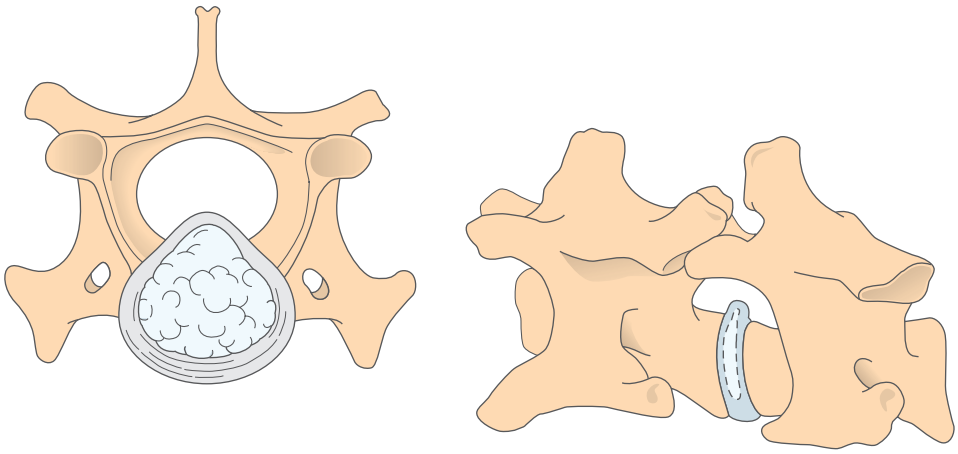

FIG. 40.22 Hansen type II disc degeneration is characterized by a slow chronic protrusion of degenerate dorsal annulus fibrosus in the vertebral canal.

DIAGNOSIS

Clinical Presentation

Signalment

Hansen type I extrusions typically occur in small-breed dogs, particularly the chondrodystrophic breeds (e.g., dachshund, beagle, bassett hound, shih tzu, Pekingese, Lhasa apso). The dachshund is by far the most commonly affected breed. Hansen type II disc protrusions typically occur in nonchondrodystrophic, larger breed dogs. Either type of disc disease can occur in any breed of dog, however, and both types have been reported in cats. Large dog breeds that seem to be most commonly encountered with type I disc extrusions include mixed breed dogs, German shepherds, Labrador retrievers, Doberman pinschers, and Rottweilers.

Hansen type I extrusions typically occur in dogs 3 years of age or older (peak ages in small dogs of 3–6 years) but may occur in dogs younger than this. A wide age range has been reported for type I disc extrusions in cats; they often occur in older patients. Hansen type II protrusions typically occur in dogs 5 years of age and older. A number of small and large breeds comprising a wide age range have been reported with HNPE of the cervical region; most of the reported cases were older dogs (median age, 9 years).[3–9]

History

Historical complaints related to type I and type II cervical disc disease include primarily neck pain and abnormal ambulation with all four limbs (tetraparesis, tetraplegia). Neck pain alone is the most common historical complaint, but it is often combined with historical evidence of a thoracic limb root signature. Some dogs have a history of unilateral neurologic dysfunction (i.e., hemiparesis). Hansen type I disc extrusion usually causes rapidly developing clinical signs (minutes to days), whereas Hansen type II disc protrusions typically cause chronically developing clinical signs (weeks to months, sometimes years). Owners sometimes mistake paroxysms of pain due to type I disc extrusions with seizure activity. In this scenario, the dog screams in apparent pain and falls over. HNPE cases are characteristically peracute to acute and tend to cause fairly severe neurologic dysfunction (nonambulatory tetraparesis or tetraplegia), often without obvious evidence of cervical hyperesthesia; this contrasts with typical calcified type I extrusions, which commonly lead to substantial cervical hyperesthesia that is less frequently associated with severe neurologic dysfunction.[3–9]

Physical Examination Findings

In small-breed dogs, type I cervical disc disease usually affects cranial cervical discs (C2–C3 most commonly) and typically causes severe neck pain, usually with inapparent or mild neurologic deficits. In one large retrospective study of 187 small-breed dogs with surgically managed type I cervical disc extrusions, several breed-related differences in extrusion sites were identified; dachshunds, beagles, shih tzus, and Pekingese were more likely to extrude discs at C2–C3, whereas caudal disc extrusions (C5–C6, C6–C7) were more likely in Yorkshire terriers and Chihuahuas. Yorkshire terriers and shih tzus were found to be older than other breeds at the time of surgery and also had a higher number of extruded discs.[10] In large nonchondrodystrophic dogs, the most common site for type I cervical disc extrusions is at the C6–C7 intervertebral disc space; these dogs also tend to present with acute onset of severe neck pain. In our experience, neck pain tends to be more severe with cranial versus caudal cervical disc extrusions. The patient often adopts a "nose-down" posture with an arched back (Fig. 40.23). When turning, these dogs tend to move the head and the neck as one unit rather than bending at the neck. Fasciculations of the neck musculature can often be appreciated, especially on palpation of the neck. Clinical signs of a root signature may be apparent. HNPE most commonly affects the C3–C4 and C4–C5 intervertebral discs, usually resulting in severe symmetric neurologic impairment (nonambulatory tetraparesis or tetraplegia) of acute onset (<24 hours), often without obvious cervical hyperesthesia. Type II cervical disc disease may result in clinically appreciable neck pain but rarely to the degree encountered in type I cervical disc disease. Type II cervical disc disease usually causes slowly progressive paresis. This can occur as an isolated process or as a component of CCSM. Impaired ambulatory function can range from unilateral thoracic limb lameness to tetraplegia with respiratory compromise.

Diagnostic Imaging

Historically, spinal imaging for pets with suspected disc disease consisted of plain radiographs followed by myelography (Fig. 40.24), both performed under general anesthesia. CT (or

FIG. 40.23 Typical "nose-down" posture of a dog with severe cervical pain.

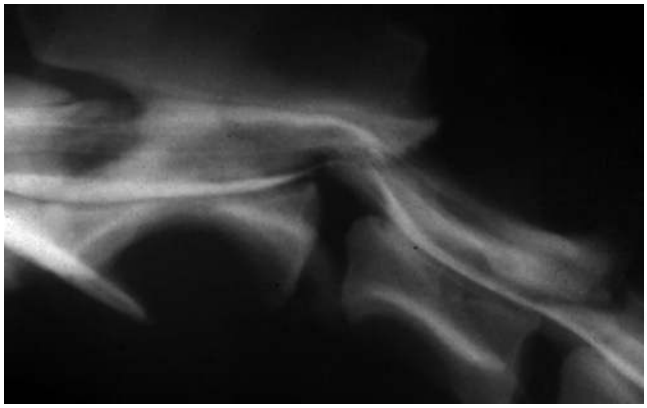

FIG. 40.24 Lateral myelographic image of a C2–C3 disc extrusion in a dog.

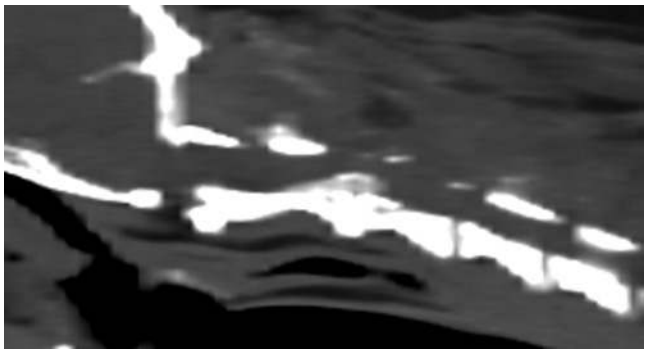

FIG. 40.25 Computed tomography sagittal reconstruction image of a dog with a cervical intervertebral disc extrusion.

CT/myelography combination) and MRI have been found to be useful imaging modalities in the diagnosis of intervertebral disc disease (Figs. 40.25 and 40.26). We consider MRI to be the current standard for spinal imaging of suspected disc extrusion/protrusion patients. In addition to providing superior anatomic detail in disc disease patients compared with myelography and CT, MRI is the best modality for diagnosing other spinal disorders that

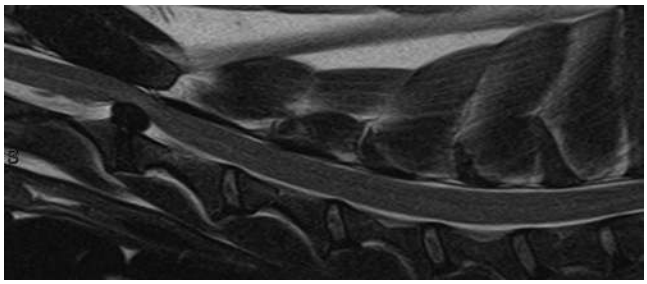

FIG. 40.26 Midsagittal T2-weighted magnetic resonance image of a dog with a cervical intervertebral disc extrusion.

may have similar clinical presentations as intervertebral disc disease and is associated with fewer side effects than myelography. Normally, the nucleus pulposus has high signal intensity on T2-weighted images (the annulus is hypointense). The nucleus pulposus of a degenerative disc is hypointense, and the distinction between the nucleus and the annulus fibrosus may be lost.

The typical imaging finding (myelography, CT, or MRI) in disc extrusion/protrusion is focal extradural spinal cord compression centered over a disc space. Sometimes, a disc extrusion will lacerate a venous sinus, leading to large extradural accumulations of hemorrhage (in addition to disc material), which can cause extensive cord compression or swelling. Occasionally, a type I disc extrusion will be lateral enough that myelographic results are normal. In such lateralized extrusions, hyperesthesia with or without unilateral limb lameness (ipsilateral to the extrusion) is a more likely clinical sign of dysfunction than overt proprioceptive or voluntary motor deficits. Another important consideration in such a clinical scenario is the presence of syringomyelia, which is not usually evident on myelography or CT imaging (requires MRI). In some cases of high-velocity concussive disc-related injury, severe motor deficits (due to a small amount of rapidly extruding disc material) may occur with minimal evidence of extradural compression on imaging studies; in such cases, evidence of spinal cord swelling is typically noted. This may be difficult to distinguish from a vascular event (see fibrocartilaginous embolic myelopathy discussion) if an imaging modality other than MRI is used. The appearance of HNPE lesions have been documented primarily on magnetic resonance (MR) images; the extruded material is hyperintense on T2-weighted images, hypointense on T1-weighted images, and may have contrast ring enhancement around the extruded material on T1-contrast (gadolinium) sequences. The extruded material is just dorsal to the dorsal annulus, between this structure and the dorsal longitudinal ligament. On axial T2-weighted images, HNPE has a characteristic "seagull" shape (Fig. 40.27). Occasionally, there may be parenchymal hyperintensity at the site of extrusion, thought to be reflective of spinal cord contusion. On CT images, HNPE material is hypodense and may exhibit peripheral ring enhancement with contrast administration.[3–9]

Laboratory Findings

Results of complete blood cell count (CBC) and serum biochemical profile analyses are typically normal. A stress leukogram may be observed on CBC results as a result of underlying disease, prior administration of glucocorticoids, or a combination of these factors. Hepatic enzyme elevations may be evident with dogs that have been treated with glucocorticoids. Urinary tract infection may be present, especially in dogs treated with

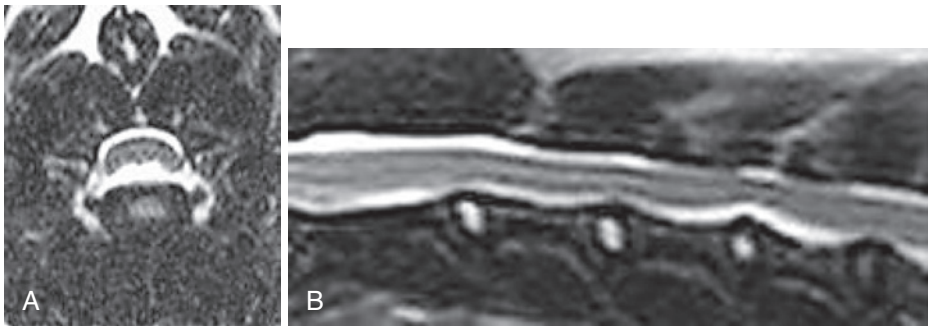

FIG. 40.27 (A) Axial and (B) midsagittal T2-weighted magnetic resonance images of a dog with a hydrated nucleus pulposus extrusion at C4–C5. Note the characteristic "seagull" appearance of the extruded material on the axial image (B).

glucocorticoids; however, pyuria and hematuria may or may not be present if the patient is still receiving steroids. Even if collected before myelography is performed, cerebrospinal fluid (CSF) is often not evaluated if clear evidence of a disc compression is present on imaging. Results of CSF analysis with type I disc extrusions are variable. Although CSF findings in type I disc extrusions have classically been characterized as normal to mildly inflammatory, moderate to marked pleocytosis with increased protein concentration is fairly common. In one retrospective study, 26 of 103 dogs (25%) with cervical disc extrusions had CSF pleocytosis ranging from 6 to 172 nucleated cells/μL.[11]

DIFFERENTIAL DIAGNOSIS

A tentative diagnosis of cervical disc disease is based on characteristic signalment, historical complaints, and clinical features. A definitive diagnosis requires spinal imaging, as well as surgical findings of extruded disc material. Other diseases that can cause similar or identical signs of cervical disc extrusion/protrusion include inflammatory/infectious conditions (e.g., corticosteroid-responsive meningitis, discospondylitis, granulomatous meningoencephalomyelitis), syringomyelia, traumatic fracture/luxation, neoplasia, and congenital abnormalities (e.g., Chiari-like malformation [CLM], AA instability, atlanto-occipital overlapping [AOO]). It is important for the surgeon to realize that, although it is uncommon, some patients with intracranial lesions will exhibit neck pain as the primary or sole clinical feature. If imaging of the cervical region in a patient with obvious neck pain is normal, imaging of the brain should be considered.

MEDICAL MANAGEMENT

Treatment of acute and chronic disc disease is a subject of considerable debate, but a number of guidelines have been established. Positives and negatives are associated with surgical and nonsurgical management of disc disease patients, and clients need to be informed of the benefits and risks associated with either approach.

Patients with suspected type I cervical disc extrusions are often first treated successfully nonsurgically if they exhibit mild to no neurologic deficits (i.e., mainly neck pain) and have not had repeated episodes of pain. Medical management traditionally consists of strict cage confinement for 3 to 4 weeks, with or without antiinflammatory medication. The cage or crate should be of such a size that the patient can change positions but cannot walk around or jump. Activity should be restricted to short walks to urinate/defecate, at which times the owner can assess the progress of the patient. Lateralized, or intraforaminal, disc extrusions are often associated with severe neck pain; however, some of these dogs may respond well to medical therapy as just described, as well as to perineural injections of glucocorticoid and bupivacaine. Medical therapy for such cases may be somewhat prolonged; in one report of 13 dogs with intraforaminal disc extrusions, 11 responded to medical management, with a median time period of 7.5 weeks to reach resolution of clinical signs without the need for analgesic drugs.[12,13] If the patient fails to improve or worsens at any time during the confinement period, surgical options should be considered.

Administering antiinflammatory drugs to a patient who is exhibiting signs of an extruded disc without concurrently confining that patient is contraindicated. Antiinflammatory drugs alleviate the patient's pain, and most dogs will subsequently become more active. Increased activity is thought to cause more pressure to be placed on the abnormal disc by adjacent vertebrae; subsequently, more disc material is extruded into the vertebral canal, and clinical signs acutely worsen. It is generally contraindicated to concurrently administer steroidal and nonsteroidal antiinflammatory drugs (NSAIDs) to disc disease patients because this combination substantially increases the chances of severe gastrointestinal complications. It is important to realize that subclinical gastroduodenal ulceration might be present in dogs with type I disc extrusions, even without administration of potentially ulcerogenic drugs (e.g., NSAIDs, dexamethasone); therefore the use of such drugs should be minimized (see also p. 428).

Traditional recommendations for medical management of dogs with type I disc extrusions have been called into question, especially those dealing with cage confinement and glucocorticoid administration. In one retrospective report evaluating medical management of dogs with presumptive type I cervical disc extrusions, no association was found between duration of cage confinement and success of medical therapy. Additionally, no beneficial effect of glucocorticoid administration on the success of medical management was found, whereas the use of NSAIDs was positively associated with successful outcome. These findings suggest that an extended cage confinement recommendation is often not adhered to by dog owners, and that it may be an unnecessary recommendation. The average confinement period was approximately 2 weeks in the aforementioned study, which may be a realistic recommendation.[14] In addition

to antiinflammatory medications, oral opiates may be considered for dogs experiencing discomfort (e.g., tramadol, 2–4 mg/kg every 8–12 hours) and/or pregabalin (2 mg/kg PO every 12 hours).

Many dogs will respond favorably to medical management. In our clinical experience, 50% to 70% of ambulatory patients with presumptive type I cervical disc extrusions (cervical or thoracolumbar) will have an initial positive response to medical therapy, although many of these dogs tend to have recurrence of clinical signs. In the aforementioned retrospective study, sustained success was achieved with medical management in approximately half of patients, whereas initial success with subsequent disease relapse was experienced by approximately 30% of dogs. Medical failure was considered a failure from the onset of its institution in 18% of cases. The mean follow-up time from onset of disease until collection of data was approximately 3 years.

Based on a limited number of reported cases, medical therapy appears to be successful for managing dogs with HNPE; it has been suggested that the biochemical nature of the extruded material in these dogs allows for more rapid resorption compared with calcified disc material.[3–9]

Type II disc disease that is not associated with cervical spondylomyelopathy (CSM) is typically managed medically with restricted activity and antiinflammatory drugs. When surgical intervention is indicated for a disc disease patient, spinal imaging and CSF analysis are typically performed on the anesthetized patient immediately before surgery. Disc fenestration is considered to be an optional ancillary surgical procedure. Fenestration involves removing a segment of annulus fibrosus so that future extrusions will likely occur through that opening rather than into the vertebral canal. Fenestration is performed in the ventral aspect of the disc in the cervical region and in the lateral aspect of the disc in the thoracolumbar region. Disc fenestration is considered to be a prophylactic measure. The efficacy of fenestration remains to be definitively proven. At the present time, fenestration remains a potentially effective but unproven method of decreasing recurrence of disease for type I extrusions, and its use is a matter of clinician preference. Patients with type II disc disease are often controlled adequately for long periods of time with medical therapy.

SURGICAL TREATMENT

Indications for surgical intervention in patients with type I cervical disc extrusions include repeated episodes of pain, pain that is not responding to appropriate medical therapy, and moderate to severe neurologic deficits (tetraparesis, tetraplegia). These indications are guidelines; the decision regarding whether to operate or medically manage a dog with a suspected cervical disc extrusion with neck pain as the main or sole clinical abnormality should be predicated on the apparent severity of the individual patient's discomfort. Many patients with type I disc extrusions appear to be in extreme and unrelenting pain. Surgical removal of compressive disc material in such patients typically leads to immediate relief of neck pain. In addition, we have found that ventrally extruded type I disc material is most readily removed from a ventral slot early in the course of the dog's clinical signs. Adhesions between the extruded material and surrounding structures develop over time, so delayed ventral slot surgery (after 3–4 weeks) may not be as effective in relieving clinical signs. The extruded material is often very hard and immovable in such cases, and venous sinus hemorrhage can be extensive. In situations in which the dog's history of neck pain is protracted (several weeks or longer), it may be more logical to perform a dorsal decompression rather than chance a potentially ineffective ventral slot attempt. An acutely tetraplegic patient should be handled as a surgical emergency with deterioration in neurologic status, whether or not the patient is still ambulatory. The surgical procedure of choice for cervical disc extrusion is usually a ventral slot procedure. Occasionally, a dorsal laminectomy is indicated for cervical disc extrusions in which dorsal or lateral accumulation of disc material or extensive spinal cord swelling is observed. A high success rate has also been reported with surgical management of dogs with HNPE, based on a limited number of cases.[3–9] Surgery is sometimes required in cases of type II disc disease; the surgical procedures employed have generally been the same as those used for type I disc disease. Specific surgical options available for CSM are discussed elsewhere in this chapter.

Preoperative Management

Preoperative management of the patient undergoing cervical spinal surgery is discussed on p. 1366.

Anesthesia

See p. 1366 for anesthetic management of the cervical spinal patient. In addition, see Table 32.1 for anesthetic considerations in the stable orthopedic patient.

Surgical Anatomy

See p. 1366 for pertinent surgical anatomy of the cervical spine.

Positioning

Patient positioning for ventral and dorsal approaches to the cervical spine is discussed on pp. 1367 and 1370, respectively.

SURGICAL TECHNIQUE

The ventral slot procedure is described on pp. 1367 to 1370. The dorsal approach to the cervical spine is described on pp. 1370 to 1373. To remove intraforaminal disc material causing nerve root compression, a dorsolateral hemilaminectomy is performed, along with partial or complete removal of the articular processes (facets). *Once the dorsal lamina is removed to the level of the articular processes, incise the joint capsule of the articular processes with a No. 11 blade, and use a No. 11 blade and Bishop-Harmon forceps to remove this tissue. Once the anatomy of the articular processes is clearly visible, drill these processes off using a high-speed air drill. Protect the lateral surface of the spinal cord during removal of the articular processes by leaving a thin shelf of bone medially as you drill in a dorsal-to-ventral direction (Fig. 40.28), while rongeuring this bone off periodically during removal of the facets (articular processes). Drill off the caudal articular process to visualize the bulk of the cranial articular process ventral to it. Drill the remainder of the cranial articular process entirely, or leave a thin layer of the process to be rongeured off. Locate the spinal nerve roots and the spinal nerve once the cranial articular process is removed. Avoid the vertebral artery, which is ventral to the nerve roots and spinal nerve. Carefully sweep beneath the spinal cord and nerve roots with a probe to remove and free disc material or hemorrhage (Fig. 40.29).* Venous sinus bleeding may occur at this point, but these vascular structures are likely to be clearly visible. *Control venous sinus bleeding as previously described.*

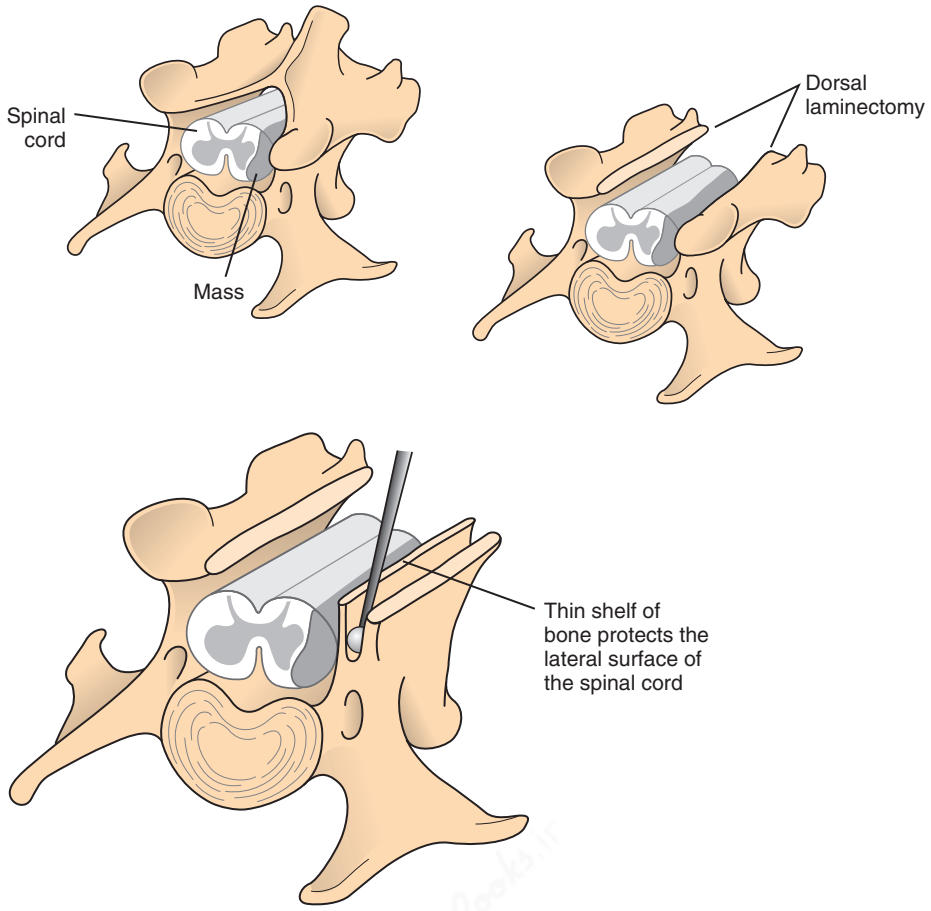

FIG. 40.28 Method of drilling off the articular processes in the cervical region while protecting the spinal cord.

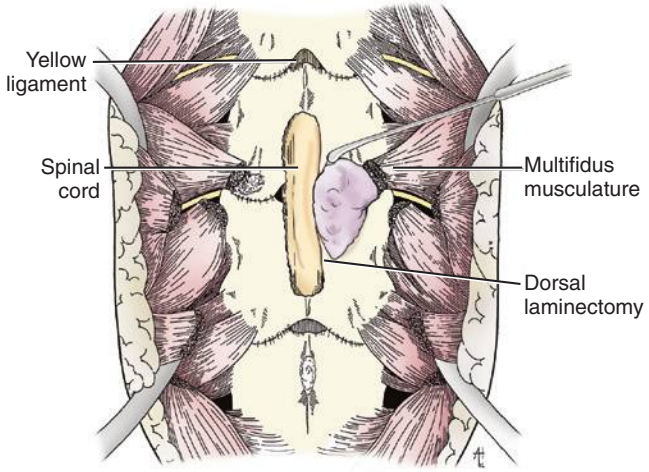

FIG. 40.29 Removal of lateralized type I disc material from a dorsal approach.

SUTURE MATERIALS AND SPECIAL INSTRUMENTS

To perform a ventral slot or a dorsal laminectomy, a high-speed air drill, Freer elevators, or Army-Navy osteotomes (large dogs), Lempert rongeurs, surgical Gelfoam, bone wax, and bipolar cautery are recommended.

COMPLICATIONS

Severe complications (e.g., loss of ventilatory ability) are rarely associated with surgery for cervical disc extrusions/protrusions. The most common complications are transient neurologic worsening after surgery and venous sinus hemorrhage (which may require transfusion). In one prospective report of 38 dogs with surgically addressed cervical type I disc extrusion, two dogs (5.2%) were euthanized in the early postoperative period due to severe aspiration pneumonia.[15] In a large (546 cases) retrospective study of dogs with cervical disc extrusions treated via ventral slot surgery, acute adverse events were documented in approximately 10% of the patients. These adverse events were considered to be major in 6.4% of cases (deterioration in neurologic status, persistent pain, intraoperative hemorrhage), and roughly half of this group required reoperation. Adverse events in this study were associated with NSAID administration, less experienced surgeons, C7–T1 extrusions, and intraoperative hypotension.[16] In one retrospective study evaluating dogs treated via dorsal cervical decompression, seven of 31 dogs with acute cervical disc extrusions (22%) experienced some level of postoperative neurologic deterioration.[17] As mentioned earlier, these dogs typically recover completely, although they tend to have a longer convalescent period than dogs treated via the ventral slot procedure. Seromas may form after the dorsal approach to the cervical spine. These typically resolve over 1 to 2 weeks with warm compressing.

PROGNOSIS

The prognosis for functional recovery in type I cervical disc disease patients is generally good to excellent. In one study of surgically managed type I cervical disc extrusions in small- and large-breed dogs, the overall success rate was 99%.[18] Return to ambulation following surgery for nonambulatory tetraparetic or tetraplegic small- and large-breed dogs with type I cervical disc extrusions averages approximately 1 week (range, 4.5–7 days). In general, it appears from the available literature that recurrence of clinical signs of type I disc extrusion is substantially higher for medically treated versus surgically treated cases. In the study of small- and large-breed dogs mentioned earlier, recurrence of cervical spinal hyperesthesia after surgery was documented in 10% of patients (8% in the small dog group, 13% in the large dog group).[18] However, only 4% of dogs required a second surgery (2.1% in the small dog group, 8.7% in the large dog group).[18]

Cervical type I disc extrusions severe enough to cause compromised respiratory function occur uncommonly; such cases are often associated with a poor prognosis. However, with appropriate respiratory support (i.e., ventilator therapy) after surgery, most of these cases are likely to recover ambulatory function within 2 to 3 months. As the prognosis for HNPE cases appears to be favorable overall with medically and surgically managed cases, it is currently difficult to make generalized recommendations for treating these patients.

CERVICAL SPONDYLOMYELOPATHY (WOBBLER SYNDROME)

DEFINITIONS

CSM is a term used to describe two distinct clinical entities in dogs. One of these is often referred to as **disc-associated CSM (DA-CSM)**, and the other is termed **osseous-associated CSM (OA-CSM)**. DA-CSM refers to a combination of vertebral malformation and malarticulation typically affecting the caudal cervical vertebrae (C5-C6, C6-C7) and associated soft tissue structures (disc, articular process joint capsules, dorsal longitudinal ligament, ligamentum flavum), usually in middle-aged to older, large- and giant-breed dogs. This disorder is typified by protrusion of the disc (type II disc protrusion) at the affected intervertebral space(s). As the name implies, OA-CSM involves primarily bony proliferation associated with the articular processes and associated joint capsules, as well as the dorsal lamina and pedicles, usually without substantial disc protrusion. OA-CSM is also associated with progressive degenerative changes and proliferation of the articular process (facet) joints, including the synovial structures. OA-CSM can affect the spine from C2–C3 through T1–T2, although caudal cervical involvement is most commonly encountered.[19–23]

GENERAL CONSIDERATIONS AND CLINICALLY RELEVANT PATHOPHYSIOLOGY

The syndrome known as CSM encompasses both DA-CSM and OA-CSM and includes a number of different anatomic abnormalities (Table 40.1). In DA-CSM, chronic instability from the malformation/malarticulation between cervical vertebrae is thought to lead to hypertrophy of soft tissue supportive structures (including the intervertebral disc) over time, with subsequent impingement of the spinal cord. This disorder is typically encountered in middle-aged to older large-breed dogs (e.g., Doberman pinscher, Rottweiler) and is considered a type of type II disc protrusion accompanied by a variable level of intervertebral instability. The main location of spinal cord compression in such cases is usually ventral, associated with the protruded dorsal annulus. The C5-C6 and C6-C7 disc spaces are most commonly involved. Congenital bony stenosis of cervical vertebrae, or OA-CSM, most commonly occurs in young (usually between 1 and 3 years), primarily large- and giant-breed (most commonly) dogs (e.g., great Dane, mastiff, Bernese mountain dog, Doberman pinscher, bassett hound, boerboel [South African dog similar to a bullmastiff]). This latter disease process is frequently included in the category of CSM, or "wobbler syndrome," but it has several distinguishing characteristics from DA-CSM. In addition to affecting cranial cervical through caudal cervical sites, the vertebral canal in these dogs is often malformed and compromised. Hypertrophy of malformed articular processes is also a common feature, sometimes accompanied by cystic enlargement of the articular process joint capsule (extradural synovial cysts). In both

TABLE 40.1 Classification of Wobbler Syndrome

Classification	Age/Breed	Lesion Location	Cause of Compression	General Prognosis
Chronic degenerative disc disease	Adult, male Doberman pinschers	Compresses ventral aspect of spinal cord C5–C7	Disc degeneration and subsequent hypertrophy of ventral annulus fibrosus	Favorable
Congenital osseous malformation	Young great Danes and Doberman pinschers	Compresses spinal cord laterally or dorsoventrally C3–C7	Congenital malformation of vertebral bodies and articular facets	Favorable to guarded
Vertebral tipping	Adult, male Doberman pinschers	Compresses ventral aspect of spinal cord C5–C7	Dorsal malposition of the affected vertebral body in the vertebral canal	Favorable
Ligamentum flavum/ vertebral arch malformation	Young great Danes	Compresses dorsal aspect of spinal cord C4–C7	Hypertrophy and hyperplasia of the ligamentum flavum; vertebral arch malformation	Favorable to guarded
Hourglass compression	Young great Danes	Compresses spinal cord on all sides C2–C7	Hypertrophy of ligamentum flavum and annulus fibrosus; malformation or degenerative disc disease of articular facets	Favorable to guarded

DA-CSM and OA-CSM, single or multiple site involvement can occur. [19–23]

DIAGNOSIS

Clinical Presentation

Signalment

As mentioned, there are two common scenarios for CSM in terms of typical signalment. Cases of caudal cervical malalignment/malarticulation, or DA-CSM, usually occur in middle-aged to older large-breed dogs, most commonly Doberman pinschers. In the OA-CSM scenario characterized by more obvious vertebral malformation, young adult giant breeds (e.g., great Dane, mastiff) are typically presented for progressive signs of cervical myelopathy. A clinical scenario similar to DA-CSM has also been described in small-breed dogs, most notably following ventral slot procedures. Instability in these dogs was likely due to excessive ventral slot size, with subsequent intervertebral instability.

History

The most common historical complaints relate to abnormal ambulation that progressively worsens over weeks to months. In many cases involving the caudal cervical region, the pelvic limbs are more notably affected than the thoracic limbs. Giant-breed dogs with OA-CSM frequently have multiple lesion sites, sometimes including cranial to midcervical involvement, and therefore occasionally display more obvious thoracic limb involvement.

Physical Examination Findings

Clinical signs of DA-CSM or OA-CSM affecting the caudal cervical region are typically consistent with a caudal cervical myelopathy, with the pelvic limbs usually more obviously affected than the thoracic limbs. If ambulatory, these patients typically exhibit a stiff, choppy, shuffling thoracic limb gait and an ataxic, wide-based, pelvic limb gait ("two-engine" gait). A thoracic limb posture characterized by elbow abduction and internal rotation of the digits (toe-in) may be appreciated in some dogs. Proprioceptive deficits are usually more appreciable in the pelvic limbs than in the thoracic limbs, and it may be difficult to distinguish these patients as having a C6-T2, rather than a T3-L3, myelopathy. Having these dogs walk with the head held in a mildly extended position may accentuate thoracic limb proprioceptive deficits. We have found that dogs with caudal CSM lesions that display subtle thoracic limb deficits are often resistant to walking with mild head extension, as if they realize they are not aware of the position of their thoracic limbs. These dogs may display neck pain, but it is often subtle. Low head carriage (flexed neck position) and resistance to lateral movement and extension of the neck may be appreciated. We have found that direct dorsal digital pressure applied to the ventral aspect of the vertebrae usually elicits discomfort in the affected cervical region(s) of dogs with CSM. Onset of clinical signs is typically slowly progressive over weeks to months, but is occasionally acute and associated with some minor traumatic event. As mentioned previously, OA-CSM patients may have cranial to midcervical lesions, and therefore may exhibit more obvious thoracic limb impairment than those patients with more caudally located lesions.

Diagnostic Imaging

The diagnostic imaging modality of choice for both DA-CSM and OA-SCM is MRI. Traction and flexed and extended sagittal MR views may provide clinically useful information in DA-CSM cases that can better identify lesions and help guide surgical planning.[24] Myelography has historically been used for both DA-CSM and OA-CSM; this imaging modality does not provide the detail afforded by MRI and often leads to transient neurologic worsening following the procedure. Myelography for DA-CSM has typically been performed using several stress (flexion, extension, linear traction) views (Fig. 40.30). These different views may be necessary (especially linear traction) to adequately define the specific abnormalities and to guide surgical decision making, if that route is chosen. Both CT and MRI have been demonstrated to be useful imaging modalities for CSM. As previously noted, MRI (Fig. 40.31), including linear traction views, for DA-CSM is preferred. In addition to providing a more detailed image of extradural compression, MRI provides valuable information regarding spinal cord parenchymal changes (e.g., edema). Hyperintense lesions of the spinal cord parenchyma on T2-weighted MRI have been demonstrated in more than half of DA-CSM Dobermans and seem to be correlated with more severe clinical presentations. Similarly, T2-hyperintense spinal cord parenchymal lesions were demonstrated in nine of 15 great Danes with OA-CSM in one study.[19] One or more of the following types of spinal cord compression at one or more disc spaces may be observed on spinal imaging for DA-CSM: ventral compression from a malaligned vertebral body; protruded dorsal annulus, or hypertrophied dorsal longitudinal ligament; dorsal compression from hypertrophied ligamentum flavum; and lateral compression from hypertrophied articular processes (facets) and associated joint capsule tissue.

Linear traction views are probably the most informative and the safest of the "stressed" views used to document whether a lesion is static or dynamic. Linear traction and flexion

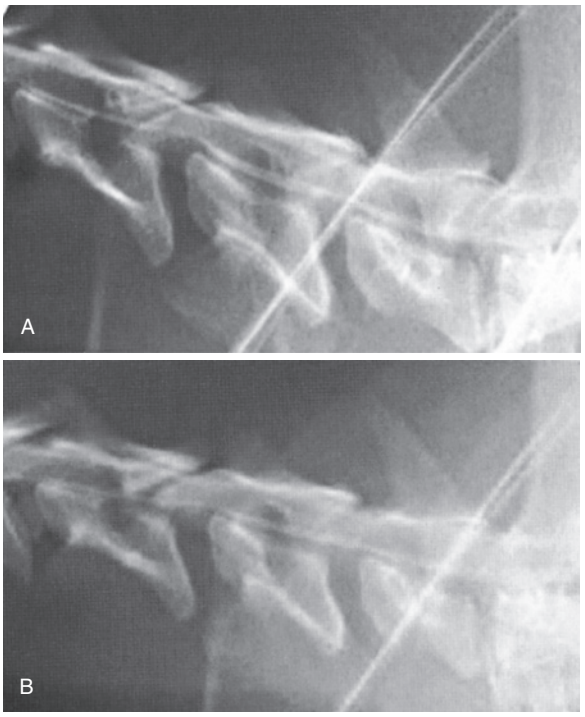

FIG. 40.30 Lateral myelographic images of a caudal cervical spondylomyelopathy lesion at the C5–C6 intervertebral disc space (A) before and (B) after application of linear traction.

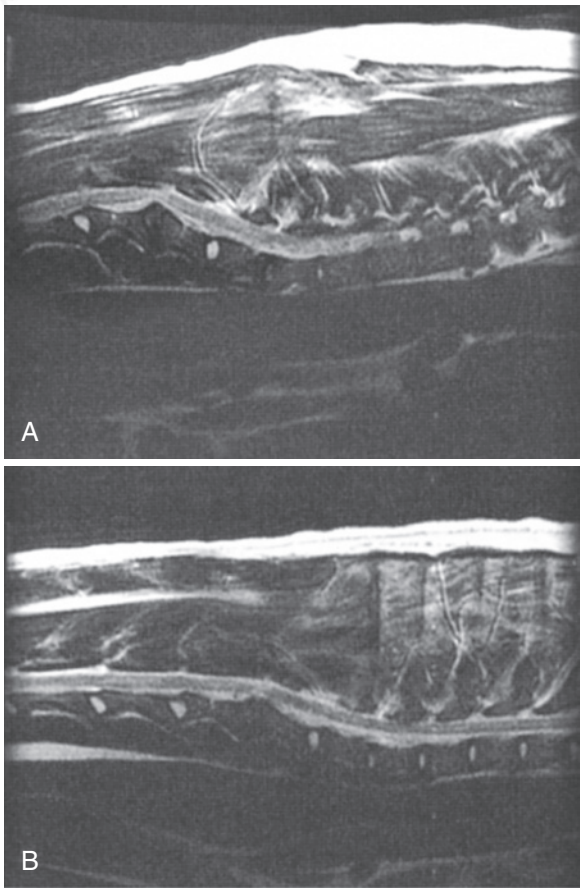

FIG. 40.31 Sagittal T2-weighted cervical spine magnetic resonance images from a dog with caudal cervical spondylomyelopathy (A) before and (B) after application of linear traction.

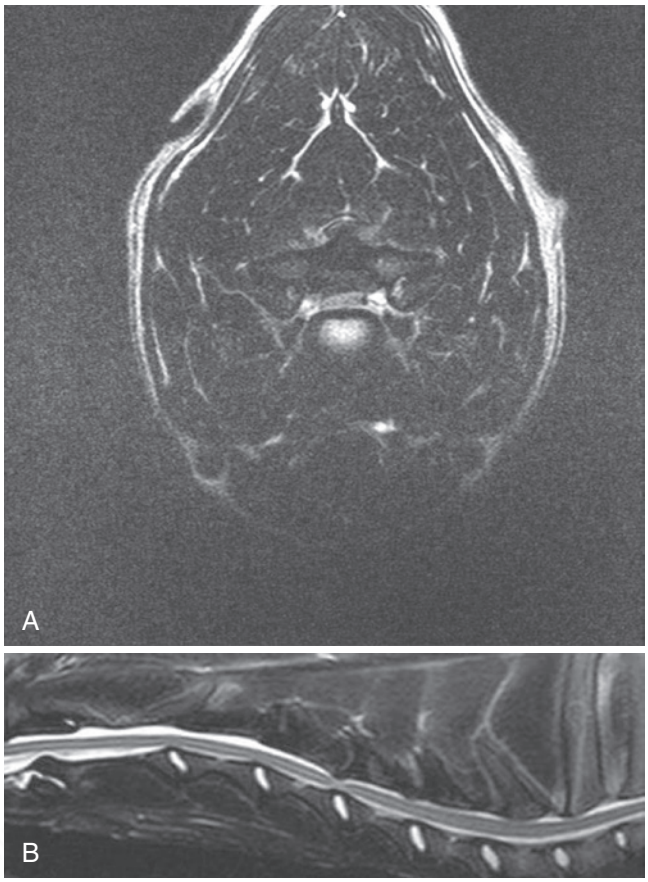

FIG. 40.32 (A) Axial and (B) midsagittal T2-weighted magnetic resonance images of a great Dane with a severely compressive osseous-associated cervical spondylomyelopathy lesion at C4–C5 and a smaller compression at C5–C6 (shown on midsagittal view).

(ventroflexed) views often relieve these compressive lesions, whereas extension views often exacerbate them. Extension views should be performed cautiously; the information gained from such views may not be worth the potential trauma they may induce. Change in the character of the lesion(s) with different views suggests that it is a dynamic, rather than a static (e.g., isolated type II disc protrusion), disorder. However, interpretation of these additional images is highly subjective, especially in cases in which lesions improve but do not dissipate on linear traction views. In many cases, assessment of whether a cervical lesion is static or dynamic is based on a number of clinical factors (e.g., history, degree of hyperesthesia), in addition to evidence of posttraction alleviation of spinal cord compression on imaging studies. MRI abnormalities typically observed in OA-CSM cases include bony abnormalities associated with the articular processes and associated joint capsule (e.g., joint capsule proliferation, extradural synovial cysts), as well as compressive bony abnormalities of the pedicles and lamina (Fig. 40.32). Spinal cord compression at these abnormal articulations is typically dorsolateral or lateral and is frequently bilateral. Stenosis of the intervertebral foramina at affected sites is also a common observation. As mentioned, T2-hyperintense parenchymal lesions are often visualized at the compression site(s). Most dogs with OA-CSM have more than one site of compression evident on MR images.[19–23]

In addition to the ambiguities associated with interpretation of traction views, one study comparing clinically normal Doberman pinschers with those with clinical signs of DA-CSM reported that four of 16 clinically normal dogs had MRI evidence of spinal cord compression. Twelve of these "normal" dogs had evidence of disc degeneration, and 11 had evidence of foraminal stenosis. The clinically affected dogs had significantly smaller vertebral canals and wider disc spaces than their clinically unaffected counterparts. These findings suggest that a relative vertebral canal stenosis combined with potentially more disc material protruding into the comparatively narrow vertebral canal may represent predisposing factors for Doberman pinschers with clinically apparent DA-CSM. In one study, transcranial motor evoked potentials elicited from the cranial tibial muscle in Doberman pinschers were found to be predictive of both MRI lesions and clinical disease due to DA-CSM.[25,26] Similar to DA-CSM, MRI abnormalities consistent with OA-CSM can be observed in clinically normal great Danes; however, there are distinct differences between abnormalities detected in clinically normal great Danes versus those with clinical features of OA-CSM. In one MRI study of great Danes with or without clinical signs of OA-CSM, one of 15 clinically normal dogs had obvious evidence of spinal cord compression compared with 15 of 15 dogs with clinical features consistent with OA-SCM. In this study, no clinically normal great Danes had evidence of spinal cord parenchymal T2-hyperintensity.[19] Additionally, it was demonstrated from a morphometric comparative study that clinically affected great Danes with OA-CSM demonstrate absolute vertebral

canal stenosis and severe foraminal stenosis, compared with clinically normal great Danes.[21]

Laboratory Findings

Laboratory findings are typically normal in cases of CSM. As with cervical intervertebral disc disease (see p. 1377), some mild laboratory abnormalities may be associated with prior glucocorticoid administration.

DIFFERENTIAL DIAGNOSIS

Numerous disorders other than CSM can lead to clinical features of a progressive cervical myelopathy. The most likely differential diagnoses are type II disc protrusion and neoplasia (especially in older patients).

MEDICAL MANAGEMENT

Medical treatment, consisting of cage confinement (3–4 weeks), antiinflammatory medications (e.g., prednisolone), and potentially the use of a neck brace, can be attempted in these dogs. As with other disc-associated problems, the patient should be gradually returned to normal activity over 4 to 6 weeks if the initial cage confinement therapy is successful. Surgical therapy is often pursued because CSM is typically a progressive syndrome, and medical therapy has been traditionally regarded as ineffective or effective only transiently. However, one retrospective report compared medical therapy with surgical therapy in 104 dogs with DA-CSM and found that medical therapy was often effective for the disease. Specifically, it was found that the success rate for the surgically treated group was 81% and for the medically treated group 53.5%; no significant difference was noted between these groups. In addition, 26.5% of the medically treated group stayed the same (vs. 2% in the surgical group). No significant difference in mean survival time was noted between groups (46.5 months for medically treated, 48.2 months for surgically treated).[27] Although this study strongly supports the use of medical management as a viable treatment option for CCSM, it should be kept in mind that a variety of surgical procedures were represented in the surgical group, and 78% of them were ventral slots. Although performing a ventral slot alone has been advocated by some as an adequate surgical procedure for CCSM, the literature suggests a lower success rate and higher recurrence rate with this approach, in comparison with distraction-stabilization procedures.

The number of DA-CSM cases presenting for spinal imaging and surgical management has decreased dramatically over the last several years. Whether this decrease is due to improving success rates with medical management, a decrease in disease incidence in affected dog breeds, or some combination of these two factors is unknown. Conversely, the incidence of OA-CSM cases presented for spinal imaging and either medical or surgical management has sharply increased over the last several years. Medical management for OA-CSM is similar to that used for DA-CSM cases and has been demonstrated to provide long-term control of clinical signs, although neurologic deterioration is common.[23]

SURGICAL TREATMENT

Numerous surgical procedures have been advocated for dogs with DA-CSM. They fall into two major categories: ventral and dorsal procedures. Ventral procedures usually involve a ventral slot procedure at the affected space, combined with distraction-stabilization; this is often combined with cancellous bone grafting at that space. Dorsal laminectomy is generally considered to be the procedure of choice for OA-CSM and is also preferred in some cases of multiple site DA-CSM.

Preoperative Management

Preoperative management of the patient undergoing cervical spinal surgery is discussed on p. 1366.

Anesthesia

See p. 1366 for anesthetic management of the cervical spinal patient. In addition, see Table 32.1 for anesthetic considerations in the stable orthopedic patient.

Surgical Anatomy

See p. 1366 for pertinent surgical anatomy of the cervical spine.

Positioning

Patient positioning for ventral and dorsal approaches to the cervical spine is discussed on pp. 1367 and 1370, respectively.

SURGICAL TECHNIQUE

Ventral Procedures (Distraction-Stabilization)

Commonly employed distraction-stabilization procedures include pin or screw placement into vertebral bodies with a PMMA bridge, and PMMA "plug" insertion into the distracted ventral slot. We prefer a combination procedure utilizing the two techniques (Fig. 40.33).

After performing a ventral slot as previously described, undercut the cancellous bone with an angled burr guard and a 2-mm burr at the cranial and caudal aspects of the slot (Fig. 40.34). These divots will help hold the PMMA in place. *Put a small, thin fat graft over the spinal cord at the bottom of the slot. With an assistant providing traction via a rope around the upper canine teeth, place a small amount of PMMA into the slot, working it into the previously drilled divots with Freer elevators.* The PMMA should have a doughy consistency and should not be sticky when inserted into the slot.

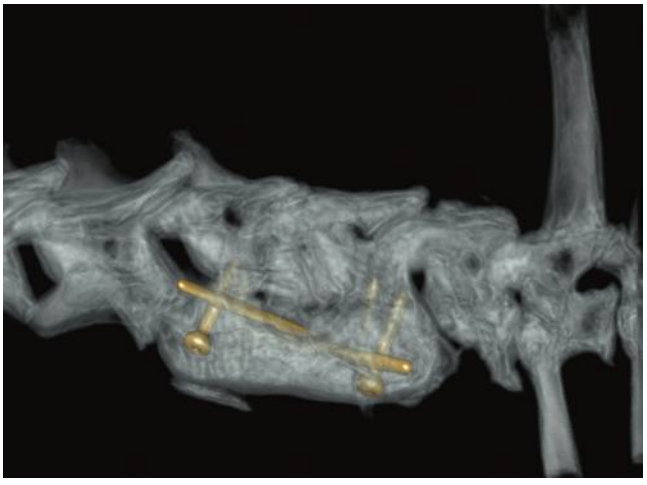

FIG. 40.33 Lateral view of a postoperative three-dimensional computed tomography reconstruction of a caudal cervical spondylomyelopathy lesion surgically addressed via a distraction-stabilization procedure.

Lavage the surgical site copiously with cool saline as the PMMA plug hardens. Once the PMMA plug has hardened, have the assistant slowly release the applied traction. The PMMA plug will maintain distraction during the remainder of the procedure.

Using a 2-mm burr, drill two guide holes through the outer cortical bone of each ventral vertebral body, angling the hole at approximately 30 to 35 degrees from midline, starting the hole just lateral to midline. Self-tap 4-0, 22 mm (small-frame Doberman) to 24 mm (large-frame Doberman) partially threaded cancellous bone screws through these guide holes to approximately the level of the last thread (Fig. 40.35). Intraoperative radiographs are often helpful in determining proper screw depth. Once the screws have been inserted, place premeasured segments of intramedullary (IM) pins (e.g., 0.062-mm pins) across the screw heads to serve as extra support (Fig. 40.36). Finally, place a PMMA bridge over the screws and crossed IM pins, molding it with Freer elevators as it hardens. Close the incision routinely. Several modifications of this procedure can be performed, depending on surgeon preference. IM pins rather than screws can be used (Fig. 40.37). The potential advantage of IM pins is bicortical bone purchase with a stronger mechanical construct than cancellous screws. A potential disadvantage is inadvertent penetration of the vertebral canal or intervertebral foramen. Cortical screws or fully threaded screws can be used, and predrilling and tapping can be performed, depending on surgeon preference. Some surgeons prefer to stop the ventral slot for this procedure once the level of inner cortical bone is reached. We prefer to remove as much of the compressive fibrous material as possible; therefore a full slot is performed. The potential for insertion of PMMA into the vertebral canal exists with a complete ventral slot, but this is very unlikely if the PMMA is placed cautiously and at the right consistency (i.e., not liquid). Application of a spinal plate (polyvinylidene plate, cervical spine locking plate) to the ventral vertebral bodies with distraction and cancellous bone grafting has also been described (Figs. 40.38 and 40.39). With the cervical spine locking plate procedure, vertebral end plates are preserved and discectomy is performed rather than a ventral slot. Distraction during these ventral procedures can be provided by using a modified Gelpi retractor placed in predrilled holes in adjacent vertebrae.

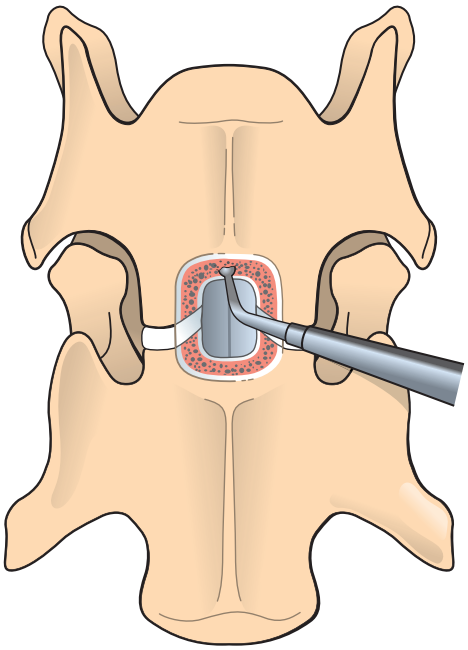

FIG. 40.34 Undercutting the ventral slot with an angled burr guard before placement of a polymethylmethacrylate plug.

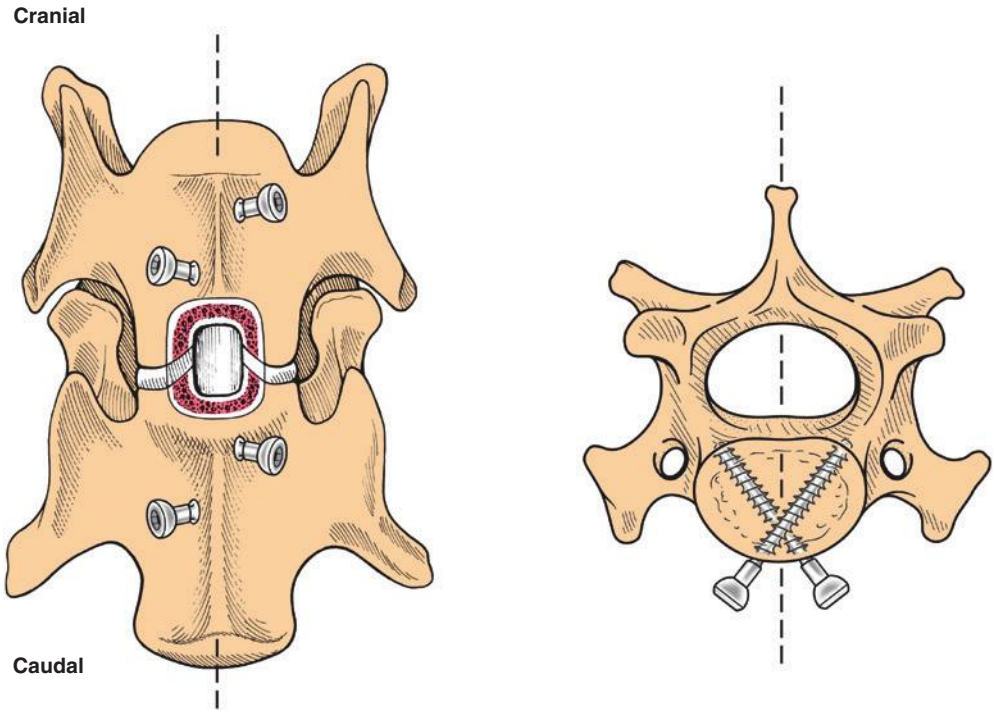

FIG. 40.35 Placement of cancellous screws in the vertebral bodies.

NOTE Do not place the points of the Gelpi retractor in adjacent disc spaces because this may weaken the discs and predispose them to instability (Fig. 40.40).

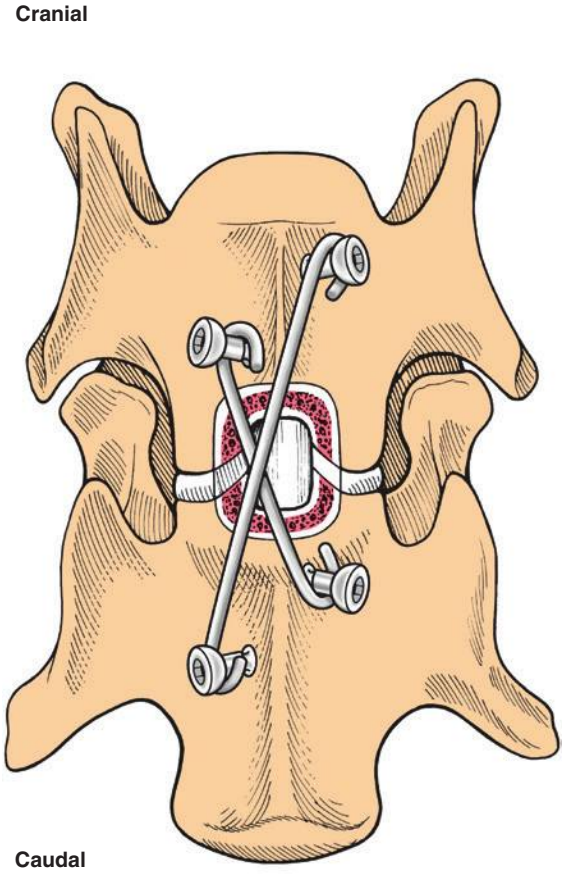

FIG. 40.36 Placement of segments of crossed intramedullary pins across the screw heads.

Dorsal Procedures (Laminectomy ± Stabilization)

Dorsal procedures involve a dorsal laminectomy for decompression, with or without articular facet screws or pins to help stabilize the joint space. The dorsal approach may be preferable when multiple disc spaces are affected or when the compression is primarily dorsal or lateral. The dorsal approach to the cervical spine is described on pp. 1370 to 1373.

To stabilize the articular processes with pins or screws, first open the joint capsule so that the articular surfaces are visualized. Using a No. 12 blade, scarify the articular surfaces of the joint. Using a mini-driver, insert the pin in the center of the caudal facet, aiming slightly laterally and ventrally and roughly perpendicular to the angle of the joint articulation. Drive the pin through the caudal and cranial facets (articular processes). Cut the pin to the desired length with a pin cutter. Stabilize the articular processes with a screw in a similar fashion, but predrill (mini-driver), tap, and measure the hole for the cortical screw before placing the screw with a screwdriver. The screw can be placed flush with the surface of the caudal facet or placed in lag fashion, or a variable amount of the proximal screw can be left extruding from the caudal facet (if it is to be used to tie in other hardware or PMMA).

Attempt to limit the pin or screw depth to just beyond the ventral aspect of the cranial facet to avoid underlying soft tissues (e.g., spinal nerve, vertebral artery). Premeasuring the distance (in millimeters) from the dorsal aspect of the caudal facet to the ventral aspect of the cranial facet on axial CT or MRI is helpful in choosing implant lengths. Facet pins or screws can be used alone (Fig. 40.41) or in combination with PMMA and Steinmann pins (Fig. 40.42).

SUTURE MATERIALS AND SPECIAL INSTRUMENTS

Basic instruments needed to perform ventral or dorsal procedures are covered on pp. 1374 and 1380. In addition to these instruments, a mini-driver, screws (± drill bits, taps, depth gauge), IM pins, specialized plates, and PMMA may be needed, depending on the specific procedures performed. Modified (blunt-ended) Gelpi retractors may also be needed for distraction.

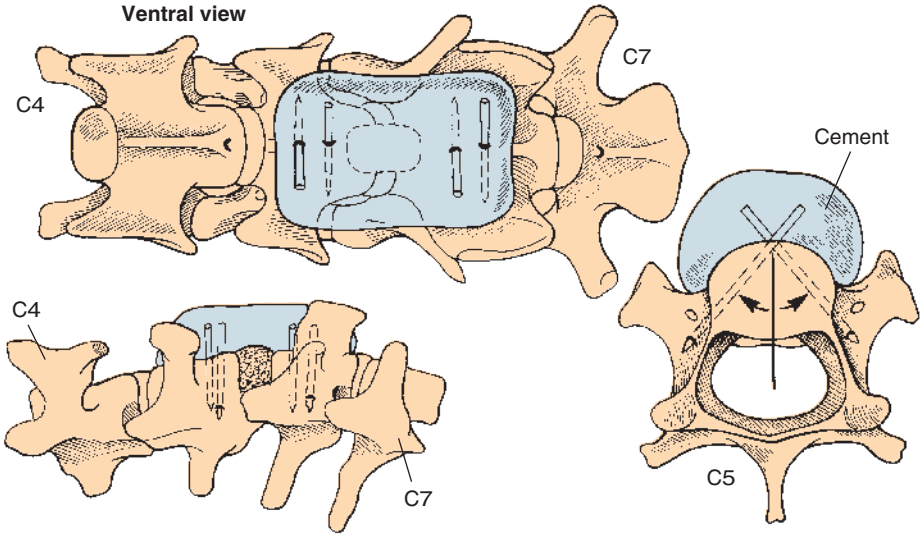

FIG. 40.37 Proper placement of Steinmann pins and polymethylmethacrylate to provide traction and stabilization to the affected intervertebral space.

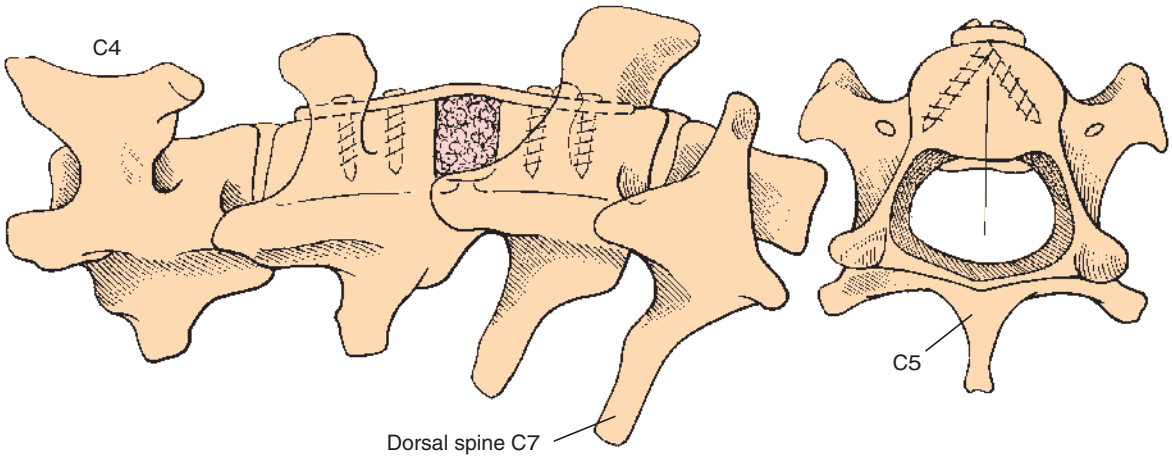

FIG. 40.38 Proper placement of full cortical allograft and polyvinylidene spinal plate to provide traction and stabilization to the affected intervertebral space.

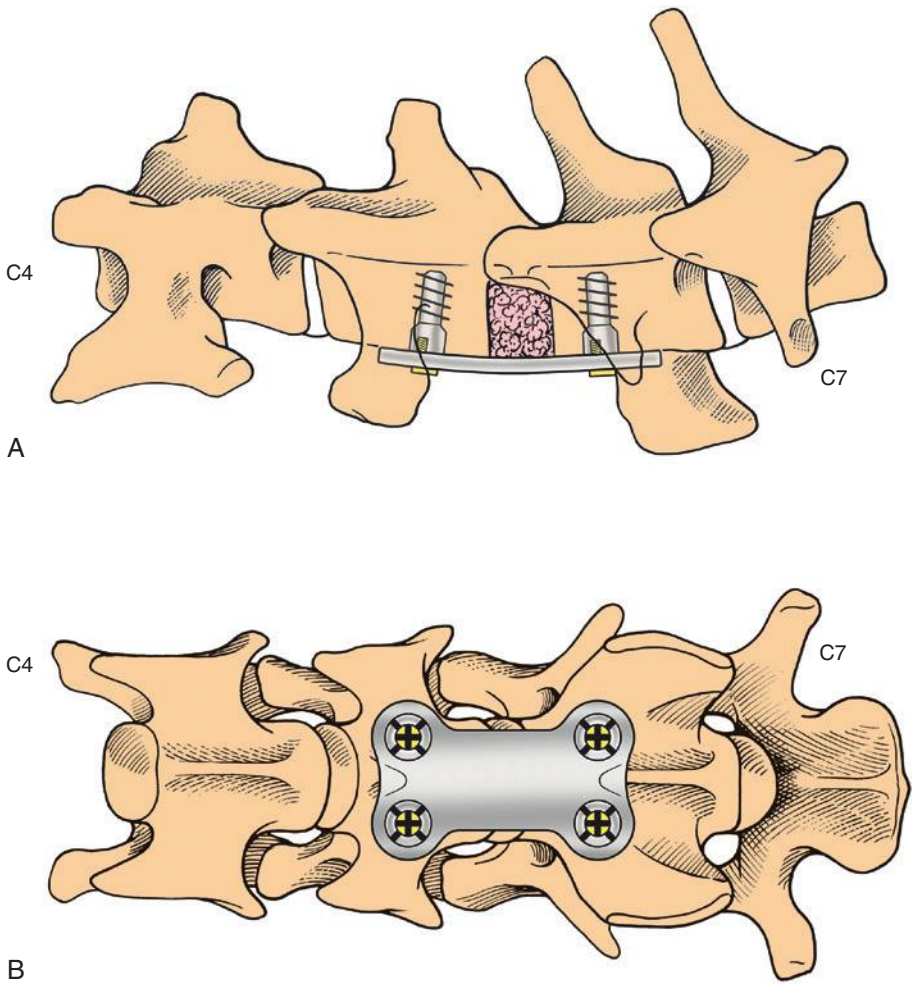

FIG. 40.39 Use of a spinal locking plate for caudal cervical spondylomyelopathy in the dog. Postoperative lateral (A) and ventrodorsal (B) views.

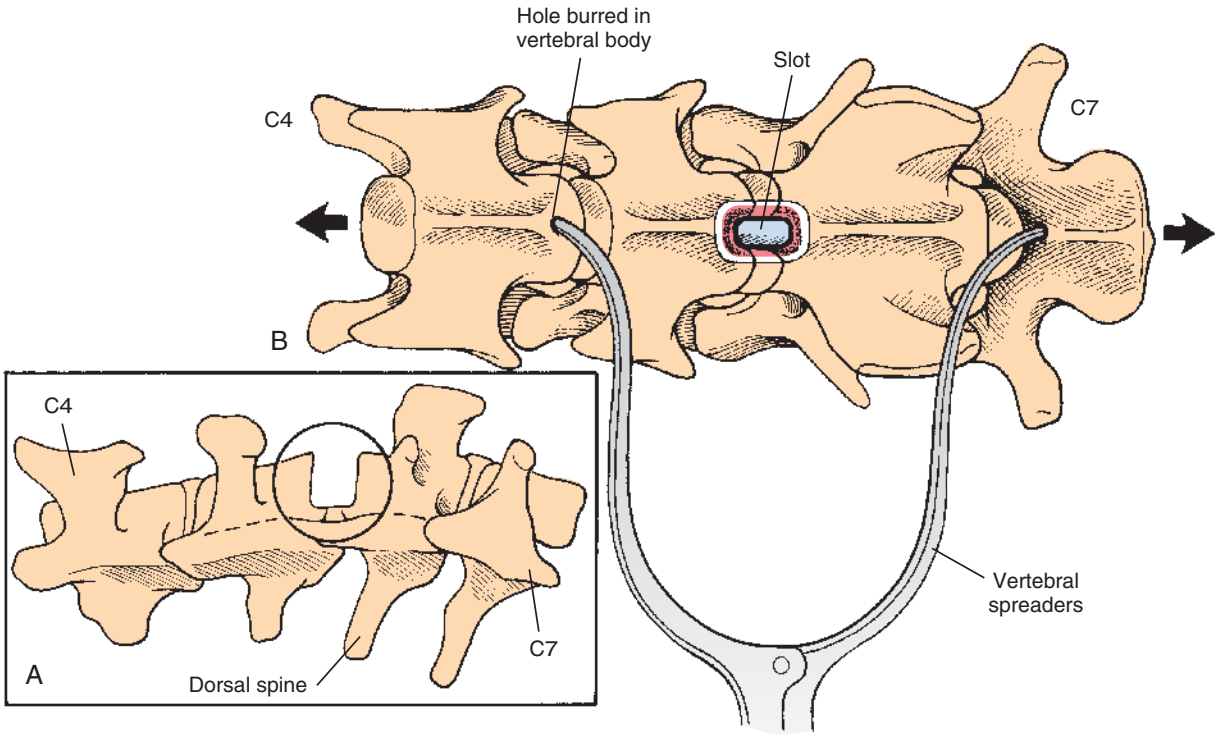

FIG. 40.40 (A) To decompress the spinal cord, perform a 75% transdiscal ventral slot at the affected intervertebral space. (B) Use vertebral spreaders to place the affected intervertebral space in 2 to 3 mm linear traction.

COMPLICATIONS

Complications associated with cervical spinal surgery are discussed on p. 1375. In addition to these complications, implant failure and infection are potential complications of distraction-stabilization procedures in DA-CSM patients. For dogs with OA-CSM treated via dorsal laminectomy, it is very common for dogs to experience transient neurologic worsening postoperatively, and some of these patients will be nonambulatory. Surgeons should be prepared to provide access to postoperative physical therapy/rehabilitation services for these dogs (see Chapter 11).

PROGNOSIS

The prognosis for dogs with both DA-CSM and OA-CSM treated surgically is generally good, but it is somewhat unpredictable compared with type I disc extrusions. Numerous reports have described various surgical procedures for DA-CSM, with success rates varying between approximately 70% and 90%. A distraction-stabilization technique using two string-of-pearl plates and a Fitz intervertebral traction screw was associated with significant neurologic improvement in 15 of 16 dogs by 6 weeks postoperatively; the majority of the dogs available for long-term follow-up had good to excellent outcomes.[28] Many dogs require a prolonged recuperative phase before regaining functional status, with attendant need for intensive nursing care. This is especially true for dogs undergoing dorsal laminectomy, which are more likely to worsen neurologically after surgery than those undergoing a ventral procedure. Although dogs undergoing distraction-stabilization procedures tend not to worsen neurologically after surgery to the extent exhibited by dogs undergoing dorsal laminectomy, prolonged recuperation is often required for these patients as well. Dogs that present nonambulatory and/or have more than one lesion on spinal imaging tend to have a less favorable prognosis than ambulatory dogs and those having only one demonstrable lesion. In general, dogs with CCSM that are ambulatory at presentation and have myelographic or CT/MRI evidence of a single affected intervertebral space have a favorable prognosis for functional recovery. The recurrence rate for DA-CSM has been reported to be up to 28% (most recent studies are <16%). The recurrence rate for the Fitz intervertebral traction screw/string-of-pearl plate procedure was 6.25%.[28] With ventral or dorsal procedures, surgical stabilization of one disc space may lead to abnormal biomechanical stresses on spaces cranial and caudal to those spaces. This is thought to lead to secondary lesions at these latter spaces over time and is referred to as the *domino effect*.

Information regarding prognosis for dogs with OA-CSM is somewhat limited compared with that available for dogs with DA-CSM. In one retrospective case series comparing medical and surgical (dorsal laminectomy) treatment of dogs with OA-CSM, it was found that long-term disease management was often achievable with either modality. Median survival for medically managed dogs in this study was approximately 3.6 years, compared with 5 years for surgically managed cases. Approximately 80% of surgically managed dogs improved neurologically and experienced good to excellent long-term outcomes. These dogs were also more likely to be euthanized for reasons unrelated

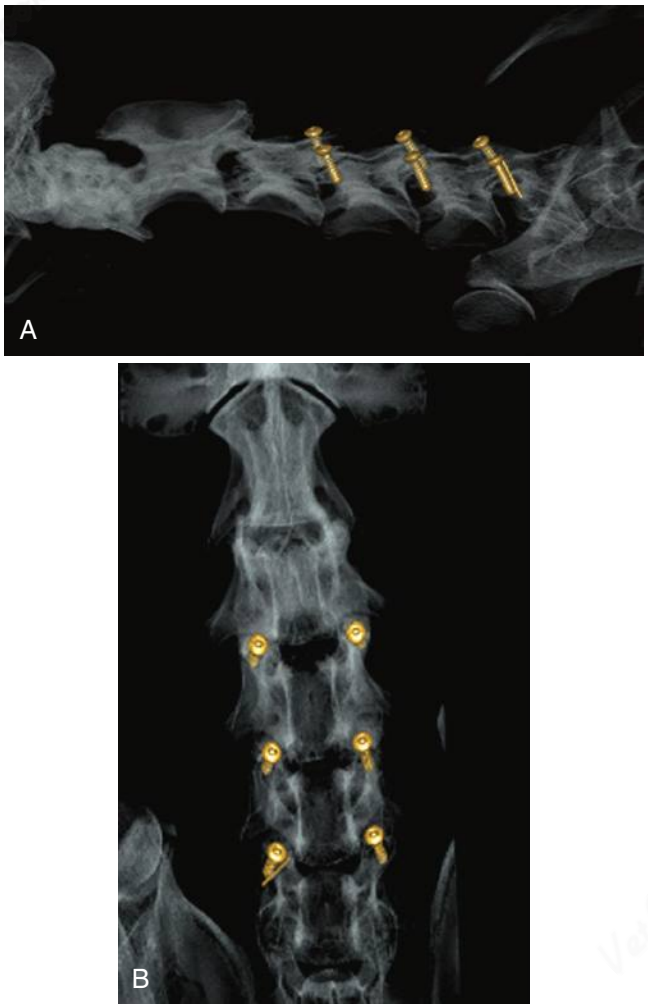

FIG. 40.41 (A) Lateral and (B) dorsal views of a three-dimensional computed tomography reconstruction, showing placement of articular facet screws in a caudal cervical spondylomyelopathy patient, following dorsal laminectomy.

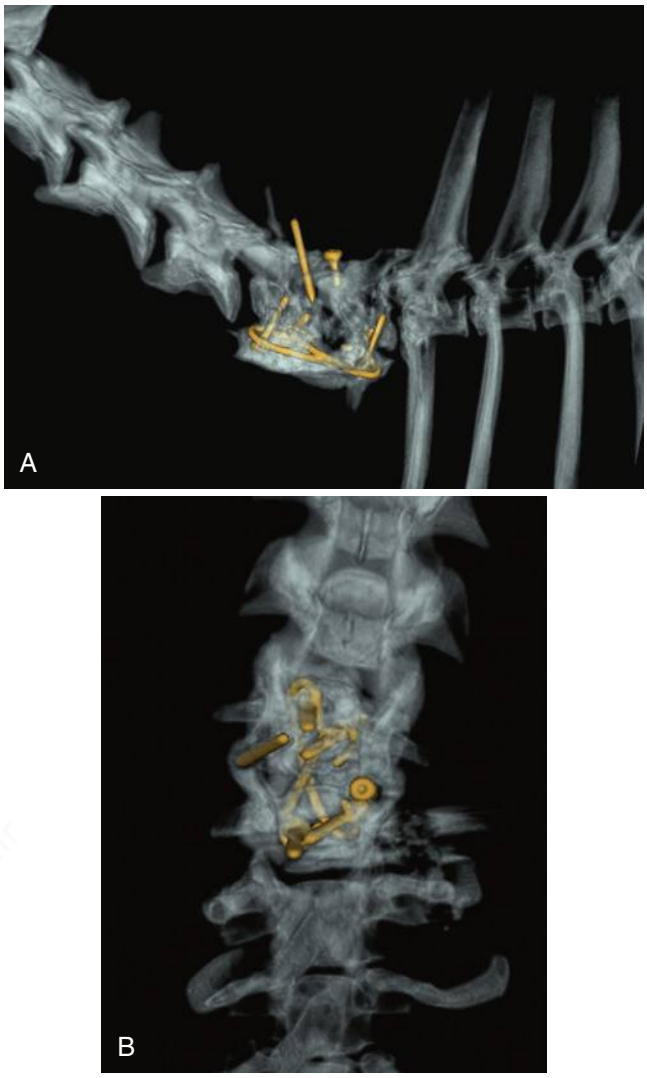

FIG. 40.42 (A) Lateral and (B) dorsal views of a three-dimensional computed tomography reconstruction, showing placement of articular facet pins, Steinmann pins, and polymethylmethacrylate following traumatic fracture/luxation.

to OA-CSM. The medically treated dogs generally worsened neurologically over time and were more likely to be euthanized due to OA-CSM.[23]

CRANIOCERVICAL JUNCTION ANOMALIES

DEFINITIONS

Craniocervical junction anomalies (CJAs) is an umbrella term used to describe a group of developmental disorders of the craniocervical junction region (supraoccipital bone, C1 and C2 vertebrae). These abnormalities include Chiari-like malformation (see p. 1353), AA instability, atlanto-occipital overlapping, and dorsal compression at C1–C2. Atlantoaxial instability refers to excessive motion at the C1–C2 joint, usually due to a hypoplastic or absent dens. **AOO** is a condition in which the atlas is displaced toward and into the foramen magnum. **Dorsal compression at C1–C2** is typically seen as soft tissue encroaching on the underlying spinal cord; this may be a reaction to instability at that joint. **Syringomyelia,** which is the accumulation of fluid within the parenchyma of the spinal cord, is usually secondary to one or more CJAs.

GENERAL CONSIDERATIONS AND CLINICALLY RELEVANT PATHOPHYSIOLOGY

AA instability is usually caused by hypoplasia or aplasia of the dens. Abnormal ligamentous support of the dens may also be involved. The instability may lead to dorsal subluxation or luxation of the axis, with resultant compression of the cranial cervical spinal cord. Associated malformations of the atlas or occipital bones may be observed in some patients. Some patients with AA instability have syringomyelia evident on MRI. An abnormality at the craniocervical junction in small- and toy-breed dogs that has recently been described is called *AOO.* In this malformation, the atlas (C1) is cranially displaced into the foramen magnum, and overlap of the occipital bone and the atlas occurs (Fig. 40.43). This displacement tends to compress the caudal aspect of the cerebellum and to elevate and compress the caudal medulla (medullary kinking). AOO is likely a form of basilar invagination. Basilar invagination is a human craniocervical junction disorder

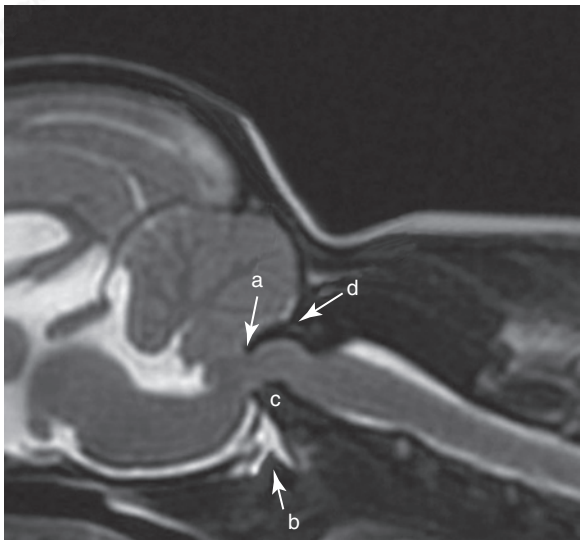

FIG. 40.43 Sagittal T2-weighted magnetic resonance image of a dog with atlanto-occipital overlapping and atlantoaxial subluxation. *a,* Cranial-most aspect of dorsal arch of C1; *b,* body of C1; *c,* dens; *d,* ventral extent of the supraoccipital bone.

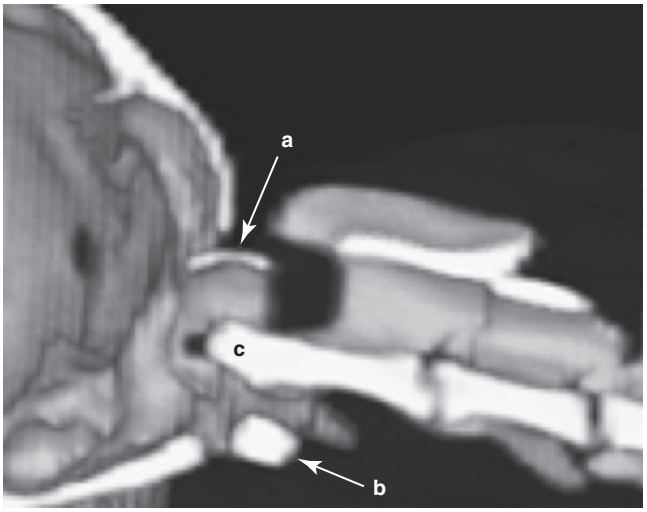

FIG. 40.44 Midsagittal reconstructed computed tomography image of the dog in Fig. 40.43, showing bony details of the abnormal anatomy. *a,* Dorsal arch of C1; *b,* body of C1; *c,* dens.

in which the atlas and the axis (C2) telescope toward the foramen magnum. We have seen this disorder as a sole entity and in combination with CLM or AA instability. Because bony detail is difficult to distinguish on MRI, it is likely that AOO has been underdiagnosed in dogs, and most cases have been incorrectly ascribed a diagnosis of CLM. The precise nature of this and other craniocervical malformations is typically apparent on CT imaging (Fig. 40.44). Similar to the AOO seen in small- and toy-breed dogs, we have seen a large number of dogs with dorsal compression at the level of C1–C2. This compression varies in severity, with some dogs having a mild divot in the dorsal subarachnoid space (Fig. 40.45) and others having severe cervical spinal cord compression (Fig. 40.46). At surgery, most of this

FIG. 40.45 Sagittal T2-weighted magnetic resonance image of a dog with a mild dorsal compressive lesion at C1–C2.

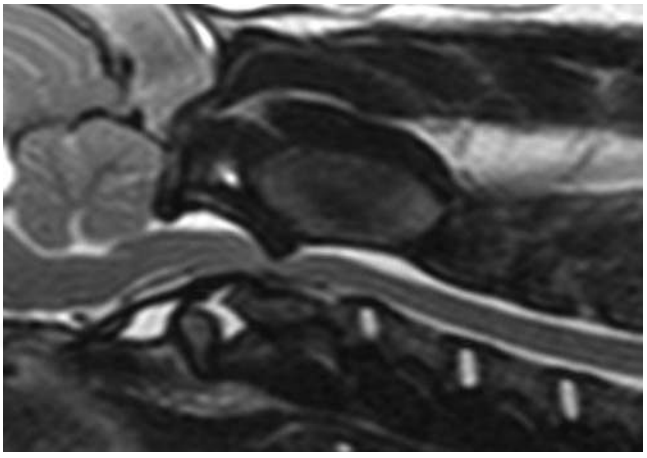

FIG. 40.46 Sagittal T2-weighted magnetic resonance image of a dog with a severely compressive dorsal lesion at C1–C2.

compressive mass appears to be soft tissue. This disorder is also likely a manifestation of instability at the C1–C2 junction, possibly a form of basilar invagination like the AOO problem. This can occur as a sole entity or in combination with CLM, AOO, or AA instability.

DIAGNOSIS

Clinical Presentation

Signalment

AA instability is usually seen in miniature and toy dogs, often younger than 2 years, but it has been reported in older dogs and in larger dog breeds. Commonly reported breeds with AA instability include Yorkshire terrier, Pomeranian, miniature and toy poodle, Chihuahua, and Pekingese. It occasionally occurs in cats. AOO and C1–C2 dorsal compression also appear to occur in predominantly miniature and toy dog breeds at young ages.

History

Historical complaints for dogs with AA instability, AOO, and C1–C2 dorsal compression typically include neck pain and varying degrees of ataxia of all four limbs. Nonambulatory tetraparesis and tetraplegia occur in severe cases.

Physical Examination Findings

Dogs with these CJAs typically display evidence of cervical (neck) pain and often have varying degrees of tetraparesis. Some dogs may also have evidence of paraspinal pain locations other than the cervical region, suggesting the presence of syringomyelia in those areas.

Diagnostic Imaging

In most cases of AA instability, the abnormality is apparent on lateral radiographs of the neck (Fig. 40.47). Stressed views may be used to demonstrate AA instability, but they must be obtained with caution. Overzealous flexion of the neck to demonstrate instability of the C1–C2 joint space may have disastrous results. MRI is both safer for this disorder and preferable to radiographs in that concurrent craniocervical junction abnormalities and syringomyelia will also be identified if present (Fig. 40.48). MRI does not provide very good bony detail. In cases of CJA, we have found that MRI followed by CT imaging of the abnormal region at the craniocervical junction is often necessary to fully characterize the abnormal anatomy.

FIG. 40.47 Lateral radiograph of a dog's cervical spine, showing atlantoaxial joint instability.

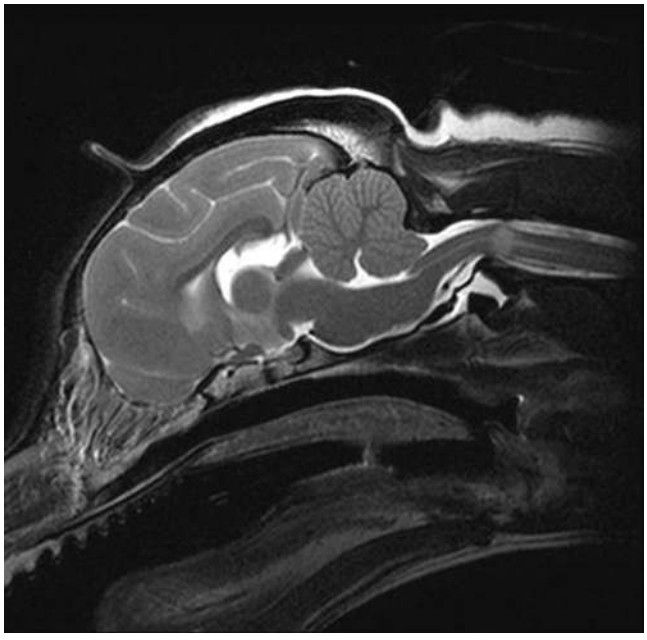

FIG. 40.48 Sagittal T2-weighted magnetic resonance image of a dog with atlantoaxial joint instability.

Laboratory Findings

As with other cervical myelopathies, results of CBC and biochemistry profile analysis are typically normal or indicative of prior administration of glucocorticoids. In very young patients, serum alkaline phosphatase levels may be elevated (bone isoenzyme).

DIFFERENTIAL DIAGNOSIS

The main differential diagnoses for dogs with CJAs are inflammatory/infectious disease (e.g., granulomatous meningoencephalomyelitis), traumatic luxation/fracture, and type I disc extrusion.

MEDICAL MANAGEMENT

AA instability is sometimes treated nonsurgically, often involving external splinting of the neck, with or without administration of antiinflammatory drugs (e.g., prednisolone). One retrospective study of AA dogs treated nonsurgically (all received external splinting) cited a good final outcome in 10 of 16 dogs (62.5%). Six of the dogs in this report (37.5%) died or were euthanized owing to neurologic deterioration or lack of improvement following splint removal.[29] In this study, the only factor significantly associated with outcome was length of clinical signs prior to therapy; dogs affected for less than 30 days were more likely to have positive outcomes than dogs affected for longer than 30 days. Reported cases of AOO or C1–C2 dorsal compression in the literature have been insufficient to allow general recommendations concerning therapy. Although most dogs with these malformations respond temporarily to medical management (similar to dogs with CLM), some dogs require surgical stabilization for relief of clinical signs.

SURGICAL TREATMENT

Surgical stabilization is the preferred treatment option for dogs that have clinical signs of neurologic dysfunction due to AA instability. Two main methods can be used to stabilize the AA joint, ventral and dorsal, with a number of variations available for each method. We do not recommend dorsal stabilization for AA instability as a primary mode of fixation; limited bone is available for implants, suture and wire fixation methods are prone to failure, and threading suture or wire beneath the atlas in a toy- or miniature-breed dog with a cranial cervical and/or caudal medullary constriction poses an unnecessary risk to the patient.

Preoperative Management

Preoperative management of the patient undergoing cervical spinal surgery is discussed on p. 1366.

Anesthesia

See p. 1366 for anesthetic management of the cervical spinal patient. In addition, see Table 32.1 for anesthetic considerations in the stable orthopedic patient.

Surgical Anatomy

See p. 1366 for pertinent surgical anatomy of the cervical spine.

Positioning

Patient positioning for ventral and dorsal approaches to the cervical spine is discussed on pp. 1367 and 1370, respectively. In cases of suspected or known AA instability, it is extremely important to limit the patient's head and neck movement while under anesthesia and during patient positioning.

SURGICAL TECHNIQUE

The ventral approach to the C1–C2 space is described on p. 1344.

With a No. 11 or a No. 12 blade, incise the C1–C2 joint capsules bilaterally, exposing the articular surfaces. Incise the soft tissue attachment between C1 and C2, revealing the underlying dens (if present) and spinal cord. Sharply dissect redundant joint capsule tissue with a No. 11 blade and Bishop-Harmon forceps. Using a small towel clamp at the C2-C3 disc space or a speed-lock reduction forceps on the body of C2, lever the C1–C2 joint into reduction (Fig. 40.49). Typically, the cranial aspect of C2 is displaced in a cranioventral direction from the surgeon's perspective (ventral approach), craniodorsally from an anatomic perspective. *Apply mild but steady traction dorsally and caudally on C2 while putting slight downward pressure on the ventral arch of C1 to attain reduction. Distract the joint spaces a small amount and scarify the articular surfaces with a No. 12 blade. While maintaining reduction, place a pin or screw through the articular processes (facets) on one side.* In most toy and miniature dogs, the pin size will be 0.035 or 0.045 mm and the screw size will be 1.5 or 2.0 mm. *Insert the pin or screw in a medial-to-lateral direction, following the plane of the joint articulation, at an approximately 45-degree angle to the vertical plane (Fig. 40.50). Release the towel clamp or reduction forceps. Insert a pin or screw through the C1–C2 joint on the opposite side, using the same technique as the first side. Place additional pins or screws in the wings of C1 and the body of C2, taking care to direct these implants laterally, away from the spinal cord (Fig. 40.51).* Depending on surgeon preference, the screws/pins can be reinforced with small Kirschner wires (K-wires) and/or cerclage wire before PMMA is placed over the implants (Fig. 40.52).

Dorsal fixation methods for the AA joint typically involve suture or wire placed under the arch of C1 and attached to C2 (Fig. 40.53). We use dorsal stabilization in cases of AA instability as adjunctive fixation when a dorsal laminectomy of C1 or C2 is required, in addition to ventral stabilization. *In this scenario, place small (1.5–2.0 mm) screws through the dorsal lamina at the edge of the laminectomy defect. For safety reasons, use a specialized drill (e.g., Anspach, Midas Rex drill) with a 1.1-mm (for 1.5-mm screws) or a 1.5-mm (for 2.0-mm screws) drill-bit attachment for safety reasons.* These specialized drills can be held in one hand like a pencil and are much less unwieldy as a mini-driver. *Insert the screws (self-tap) 2 to 3 mm, and anchor them together with small K-wires and PMMA (Fig. 40.54).*

Both ventral and dorsal methods of stabilization of the atlanto-occipital region have been described in people for basilar invagination, and we have adapted these methods to several canine patients with favorable results (Fig. 40.55).

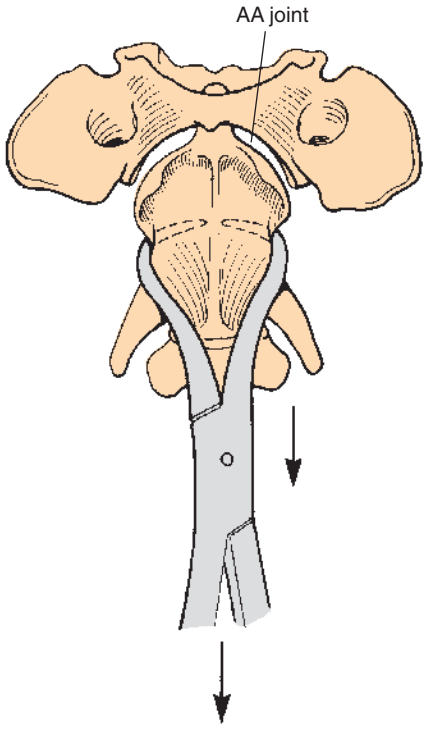

FIG. 40.49 Use orthopedic reduction forceps to grasp the body of C2. Use traction and countertraction to reduce the atlantoaxial subluxation. *AA,* Atlantoaxial.

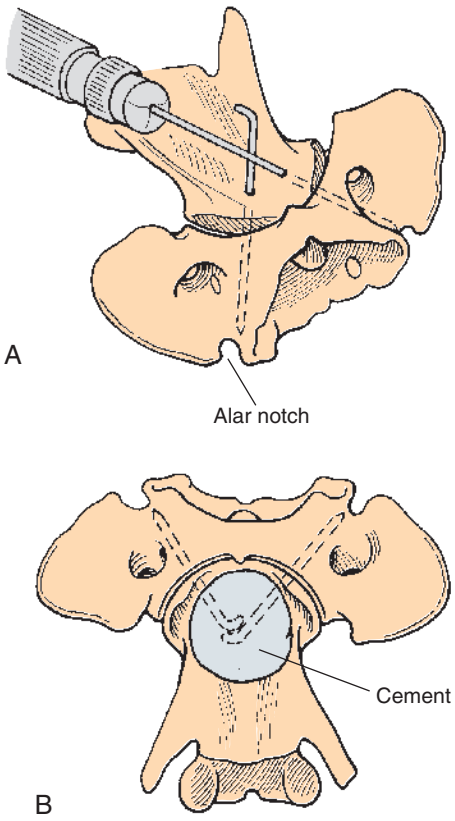

FIG. 40.50 (A) Place K-wires in cross-pin fashion; wires are directed toward the alar notch to ensure proper placement. (B) Notch or bend the exposed ends of the K-wires. Mold polymethylmethacrylate around both pin ends.

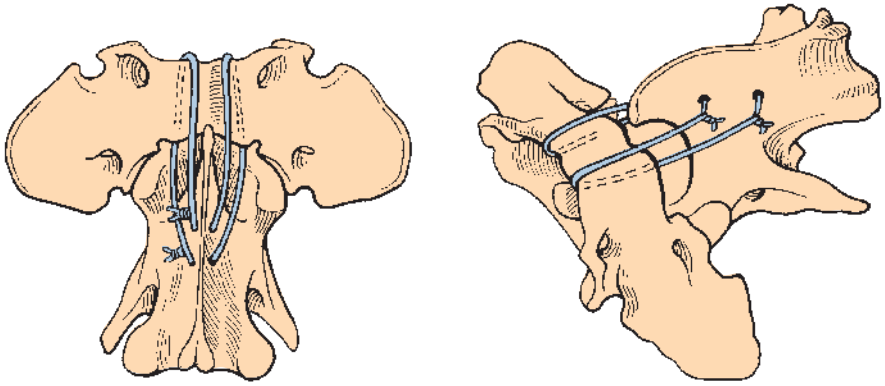

FIG. 40.53 For dorsal stabilization of atlantoaxial subluxation, pass wire or suture material under the dorsal arch of C1, then pass the wire or suture material through holes drilled in the dorsal spine of C2 and secure it.

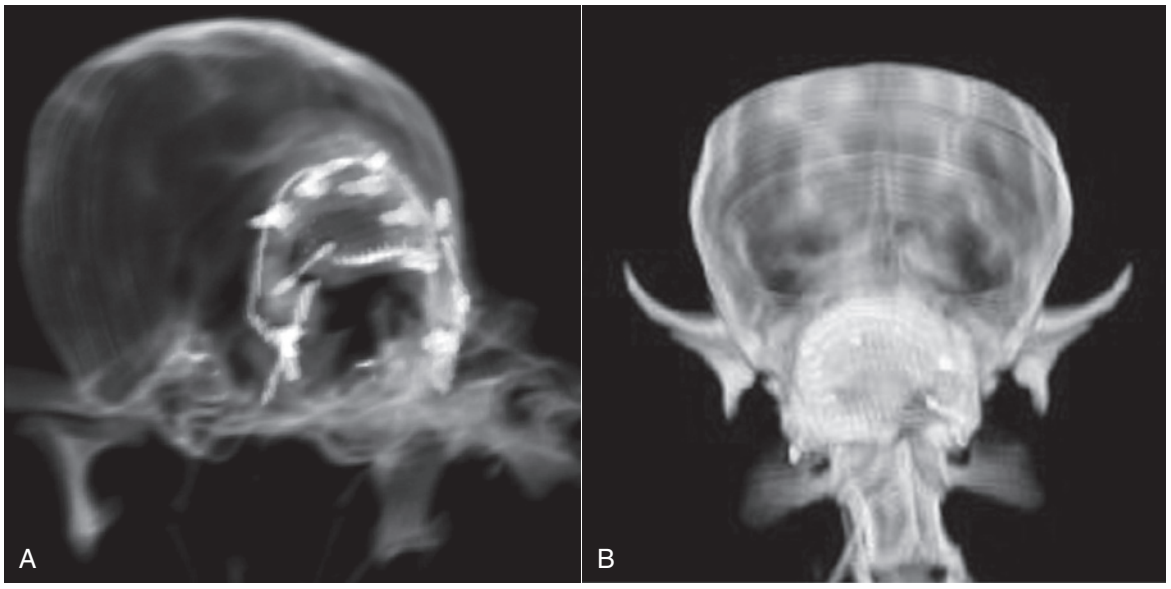

FIG. 40.55 (A) Caudolateral and (B) dorsal views of a three-dimensional computed tomography reconstruction from a dog with atlanto-occipital overlap decompressed and stabilized dorsally.

SUTURE MATERIALS AND SPECIAL INSTRUMENTS

In addition to standard instruments needed to perform a ventral or dorsal cervical approach (pp. 1345 and 1374), various surgical instruments may assist in performing surgery for CJAs. These include a specialized drill system (e.g., Anspach or Midas Rex), small (1.5–2.0 mm) screws (we typically use titanium screws in case reimaging with MRI is required in the future), small K-wires (titanium preferred), and PMMA.

COMPLICATIONS

Because of the proximity of the AA site to brainstem centers for cardiac and respiratory control, intraoperative deaths have been attributed to inadvertent damage to these medullary regions during AA stabilization. Postoperative complications involving upper respiratory function (e.g., coughing, gagging, laryngeal paralysis) occasionally occur with the ventral approach. Aspiration pneumonia is a potential postoperative complication that may be related to upper airway (i.e., laryngeal) or pharyngeal dysfunction. Anecdotally, we have found that relaxing the Gelpi retractors at frequent intervals (e.g., every 10 minutes) during surgery dramatically reduces the rate of postoperative upper airway complications. Overall, reported perioperative mortality rates for surgical management of dogs with AA instability vary from 0% to 30%, with most recent reports describing rates of approximately 5% to 10%. The complications to be expected with surgical management of AOO and C1–C2 dorsal compression are likely similar to those for AA instability; however, too few data are available regarding these surgical procedures for a complication rate to be calculated.

PROGNOSIS

Surgical success rates for AA instability vary in the literature from approximately 60% to over 90%; however, most recent reports regarding surgical treatment of this disorder describe a surgical success rate exceeding 80%. Similar to what has been reported for nonsurgical management of AA instability patients, length of clinical disease presence has been negatively associated with surgical success. Some investigators also suggest that the severity of neurologic dysfunction before surgery is inversely related to outcome; the prognosis for patients with AA instability is fair to good if mild to moderate neurologic deficits are present, and guarded if the deficits are severe (e.g., tetraplegia).

SPINAL ARACHNOID DIVERTICULUM

DEFINITION

Spinal arachnoid diverticula are typically solitary, dorsally or dorsolaterally located, focal accumulations of fluid that occur at the cranial cervical (most commonly over C2–C3 vertebral segments) or caudal thoracic regions of the spinal cord. In one large (122 dogs) retrospective study of spinal arachnoid diverticula, 65 were located in the cervical region and 60 in the thoracolumbar region.[30] Multiple or bilobed spinal arachnoid diverticula are frequently encountered, especially in the cervical region of Rottweilers. Ventrally located spinal arachnoid diverticula have also been reported.

GENERAL CONSIDERATIONS AND CLINICALLY RELEVANT PATHOPHYSIOLOGY

The old name for this disorder (spinal arachnoid cyst) is a misnomer because the lesions are actually CSF-filled diverticula of the subarachnoid space rather than true cysts. These lesions have been described as meningeal cysts, leptomeningeal cysts, spinal arachnoid pseudocysts, and arachnoid cavitations. Proposed causes of these anomalous fluid accumulations are numerous, including congenital malformation, trauma, inflammation (arachnoiditis), and neoplasia. However, an underlying cause is often not found for spinal arachnoid diverticula. Accumulated fluid causes compression of adjacent spinal cord parenchyma, resulting in clinical signs of myelopathy.

DIAGNOSIS

Clinical Presentation

Signalment

Spinal arachnoid cysts have been described in a considerable number of dogs and several cats. Rottweilers appear to be particularly predisposed to spinal arachnoid cysts in the cervical region. In this breed, dorsally located fluid accumulations in the cranial cervical regions are common. Multiple other dog breeds, including a number of small-breed dogs, have also been reported with this condition. In the large retrospective study mentioned earlier,[30] higher body weight was significantly associated with a cervical location of diverticula, there was a male predominance for the disorder, and pugs and French bulldogs were predisposed (in addition to Rottweilers). Pugs and French bulldogs were more likely to have a concurrent spinal disorder in the vicinity of the diverticulum, whereas only one of 17 Rottweilers had a concomitant spinal abnormality. Age at onset of clinical signs of neurologic dysfunction is quite variable, ranging from several months to 12 years of age. Most reported dogs developed signs of myelopathy in young adulthood. There is one report of seven young (3- to 4-month-old) pug dogs with C2-C3 diverticula and associated central canal dilation/syringomyelia of the cervical spinal cord.[31]

History

Dogs with cervical spinal arachnoid diverticula typically have historical complaints of slowly progressive ataxia and paresis of all four limbs. The reported young pug dogs initially showed signs of scuffing the dorsum of the front paws while ambulating, leading to skin abrasions; these dogs progressed to varying degrees of tetraparesis.[31]

Physical Examination Findings

Slowly progressive ataxia and tetraparesis are typical clinical features of this disorder. Dogs with dorsally or dorsolaterally located cranial cervical lesions (often Rottweilers) typically exhibit tetraparesis with hypermetria, primarily in the thoracic limbs (presumably via interference of the diverticulum with spinocerebellar tracts). Spinal hyperpathia does not appear to be a prominent clinical feature of this disorder but has been described.

Diagnostic Imaging

The diagnosis of spinal arachnoid diverticulum is based primarily on spinal imaging; myelographic diagnosis of this disorder is most commonly reported. Both CT and MRI (Fig. 40.56) have been successfully used to identify spinal arachnoid diverticula, and these modalities provide more detailed information regarding lesion lateralization and potential associated abnormalities (e.g., syringomyelia). The typical myelographic appearance is a bulbous, contrast-filled diverticulum continuous with the contrast column of the subarachnoid space, with a characteristic teardrop shape (Fig. 40.57).

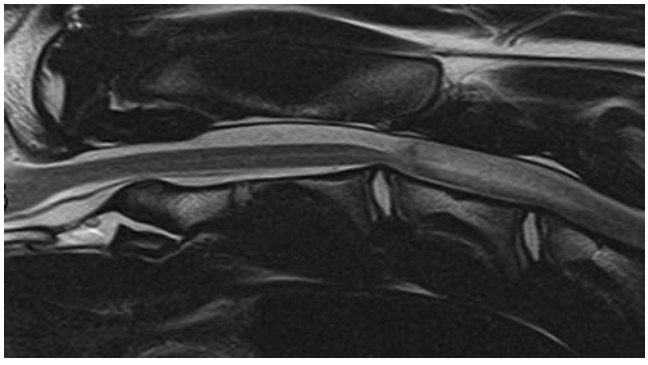

FIG. 40.56 Sagittal T2-weighted magnetic resonance images of a dog with a spinal arachnoid cyst.

Laboratory Findings

Results of CBC and biochemistry profile analysis are typically normal. Cerebrospinal analysis is usually within normal limits but may reveal a mild mononuclear pleocytosis with elevated protein concentration. Histopathology of resected "cyst" wall reveals meningeal tissue (dura-arachnoid).

DIFFERENTIAL DIAGNOSIS

The differential diagnoses for spinal arachnoid diverticula are diverse and include disc extrusion/protrusion, articular process (facet) hypertrophy, extradural synovial cyst, neoplasia, and infectious/inflammatory disease (e.g., discospondylitis). Ranking of these differential diagnoses in terms of likelihood is influenced heavily by patient age and breed.

MEDICAL MANAGEMENT

Medical management (e.g., glucocorticoid therapy) may be attempted but is unlikely to be successful in the long term.

SURGICAL TREATMENT

Surgical treatment involves resecting a portion of the meninges making up the "cyst" wall, thereby relieving the pressure exerted on underlying spinal cord parenchyma.

Preoperative Management

Preoperative management of the patient undergoing cervical spinal surgery is discussed on. p. 1366.

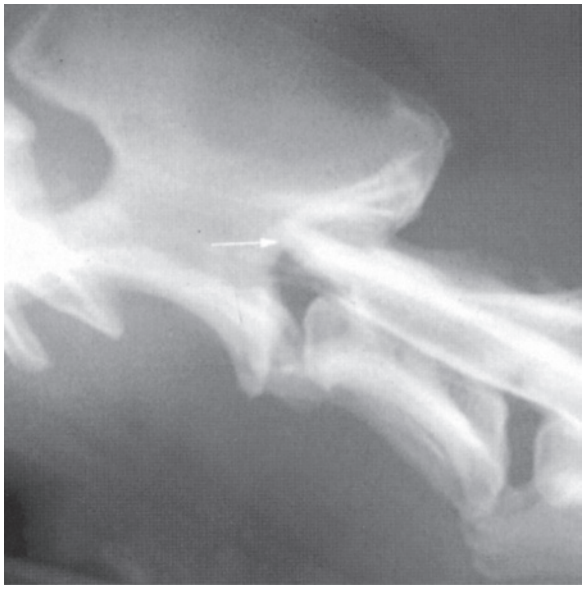

FIG. 40.57 Lateral myelographic image of a spinal arachnoid cyst *(arrow)* in the cervical region of a dog.

Anesthesia

See p. 1366 for anesthetic management of the cervical spinal patient. In addition, see Table 32.1 for anesthetic considerations in the stable orthopedic patient.

Surgical Anatomy

See p. 1366 for pertinent surgical anatomy of the cervical spine.

Positioning

Patient positioning for the dorsal approach to the cervical spine is discussed on p. 1370.

SURGICAL TECHNIQUE

Cervical spinal arachnoid diverticula may be accessed via a dorsal laminectomy (p. 1373) or a dorsolateral hemilaminectomy (p. 1379). Decompression of the spinal arachnoid diverticulum is basically a durotomy over the abnormal region, usually combined with marsupialization of the "cyst" wall. *Bend a 25-gauge needle at approximately 120 degrees, with the bevel pointing upward. Grasp the hub of the needle with a Mosquito hemostat. Use the tip and bevel of the needle to "tent up" and perforate the dura-arachnoid at the level of the diverticulum (Fig. 40.58).* CSF should flow out of the perforation. *Place the blunt, angled tip of a nerve root retractor (e.g., Gross ear hook and spoon) into the perforation site. While gently pulling up on the dura-arachnoid, advance the retractor tip linearly along the diverticulum site, incising the meninges over the metal tip during advancement using the tip of a No. 11 blade (Fig. 40.59). Once the dura-arachnoid is incised over the diverticulum, sequentially grasp the edges of the cranial and caudal aspects of the incised meninges at either end of the meningeal defect, and incise (using a No. 11 blade or fine tenotomy scissors) the meninges perpendicular to the spinal cord, creating a dorsal and ventral flap that can be reflected dorsally and ventrally, respectively. Resect a portion of one of the meningeal flaps for biopsy. Perform marsupialization by attaching the edges of the meningeal defect to surrounding epaxial musculature using fine suture material (5-0 or 6-0 polydioxanone or polypropylene), Bishop-Harmon forceps, and Castroviejo needle holders, in an interrupted pattern.*

SUTURE MATERIALS AND SPECIAL INSTRUMENTS

In addition to standard instrumentation used for dorsal cervical procedures, 5-0 or 6-0 polydioxanone or polypropylene, Castroviejo needle holders, and tenotomy scissors are useful for surgical treatment of spinal arachnoid diverticulum.

COMPLICATIONS

Complications associated with cervical spinal surgery are discussed on p. 1375.

PROGNOSIS

From the limited data available, surgical treatment of spinal arachnoid cysts in dogs and cats appears to have a good prognosis. Some evidence suggests that marsupialization of the diverticulum wall to surrounding tissues at surgery may help prevent recurrence.

SPINAL NEOPLASIA

DEFINITIONS

Spinal neoplasia refers to primary and secondary tumors of the vertebrae or spinal cord parenchyma. **Primary tumors** include those neoplasms that arise from spinal cord parenchyma (e.g., neurons, glial cells) or associated meningeal/ependymal tissue. **Secondary tumors** include tumors that arise from structures extrinsic to the spinal cord and its meningeal covering. Such tumors include primary or metastatic vertebral neoplasms, malignant nerve sheath tumors (MNSTs), and metastases to the extradural space or the cord parenchyma (intramedullary metastases).

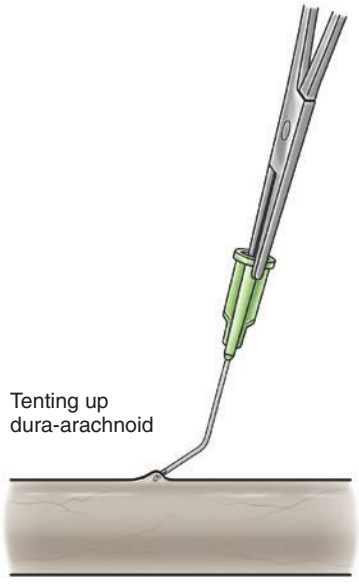

FIG. 40.58 Needle method for tenting-up the dura-arachnoid when performing a durotomy.

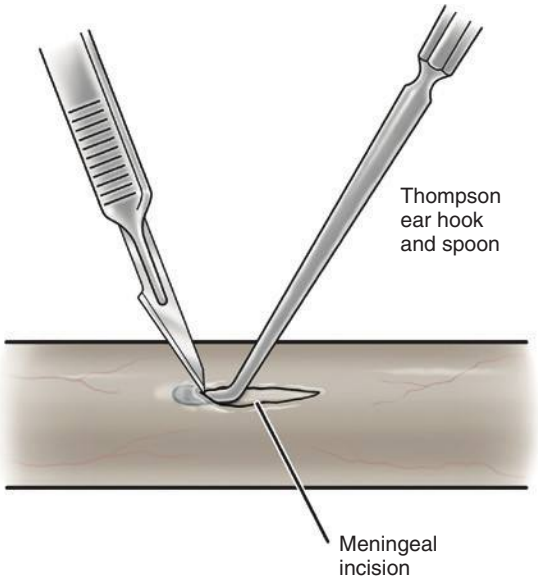

FIG. 40.59 Incision of the meninges over the tip of a probe, while the probe is advanced along the length of the diverticulum.

GENERAL CONSIDERATIONS AND CLINICALLY RELEVANT PATHOPHYSIOLOGY

Numerous tumors can affect the spinal cord of dogs and cats. As with brain tumors, tumors affecting the spinal cord can be conceptually divided into primary and secondary tumors. As with brain tumors, primary tumors are more common than metastatic tumors. It is often clinically useful to classify spinal cord neoplasms based on the relationship between the tumor and the meninges. Spinal cord tumors are typically classified as extradural, intradural/extramedullary, or intramedullary. Because some spinal tumors occupy more than one of these locations (e.g., may be both extradural and intradural/extramedullary), the additional location category of mixed compartment has been suggested. Spinal cord tumors exert their pathologic effects by causing compression or invasion of the spinal cord and by producing peritumoral edema, inflammation, and hemorrhage.

Extradural tumors represent the most frequently diagnosed category of spinal neoplasia. Extradural tumors include primary and secondary (metastatic or local invasion) vertebral and soft tissue tumors. Primary vertebral tumors such as osteosarcoma, chondrosarcoma, myeloma (plasma cell tumor), fibrosarcoma, and hemangiosarcoma are common extradural tumors encountered in dogs. Vertebral tumors reported in cats include osteosarcoma, fibrosarcoma, undifferentiated sarcoma, and plasma cell tumor. The most common primary vertebral body tumor in dogs and cats is osteosarcoma. Carcinomas account for the majority of secondary vertebral tumors in dogs. It may be difficult in some cases to ascertain whether a vertebral tumor is primary or metastatic. Other tumors may occur in the epidural space, without directly involving the vertebrae. Common among these are sarcomas, most frequently osteosarcomas and hemangiosarcomas. Lymphosarcoma can be primary or metastatic and is often located in the extradural space, particularly in cats. Lymphosarcoma is the most common spinal tumor of cats. Meningiomas and MNSTs are usually typically located intradurally but occasionally will exhibit an extradural pattern on myelography or other imaging modalities (CT/MRI). Metastatic carcinomas (e.g., mammary carcinoma, prostatic carcinoma) may localize to the extradural space. A number of fatty tumors have been reported to affect the spinal cord in dogs, including lipoma, myelolipoma, infiltrative lipoma, and liposarcoma. These all generally occur in an extradural location. Meningiomas and MNSTs are the two most common intradural/extramedullary neoplasms, with meningiomas predominating. Intramedullary tumors are infrequently encountered neoplasms that include primary spinal parenchymal tumors (e.g., astrocytoma, oligodendroglioma, ependymoma) and intramedullary metastases. The most common intramedullary metastases in dogs are thought to be hemangiosarcoma and lymphosarcoma. Mixed compartment tumors tend to occur in more than one of the three typical compartments listed previously. MNST is the most common type of neoplasm in this category, followed by lymphosarcoma and malignant fibrous histiocytoma.

DIAGNOSIS

Clinical Presentation

Signalment

In general, most patients with spinal neoplasia are older (e.g., >5 years), but some tumors (e.g., lymphosarcoma) are seen commonly in young animals. Spinal tumors appear to be much more common in larger dogs than in small-breed dogs. The median age of cats with spinal lymphosarcoma is 2 to 3 years.

History

Spinal tumors classically cause progressive signs of a myelopathy, but acute or subacute development of spinal cord dysfunction often occurs, especially with feline lymphosarcomas and intramedullary neoplasms. Rapid onset of clinical signs may be due to such factors as pathologic fracture of a cancerous vertebra, acute hemorrhage or necrosis of a tumor, or rapid growth of a neoplasm with subsequent damage to spinal cord parenchyma (more likely with intramedullary tumors). Spinal cord tumors are typically solitary and can occur anywhere along the length of the spine. Meningiomas and MNSTs arise most frequently in the cervical spinal cord, with MNSTs being especially prominent in the cervical intumescence area.

Physical Examination Findings

A prominent feature of extradural and intradural/extramedullary spinal neoplasia is spinal hyperesthesia, which often precedes the onset of proprioceptive and voluntary motor deficits. Spinal hyperesthesia is often not a prominent early clinical feature in patients with intramedullary spinal tumors, probably owing to lack of meningeal involvement. In MNSTs of the cervical intumescence, a history of unilateral thoracic limb lameness (on the side of the tumor) preceding the development of clinical signs of myelopathy is common.

Diagnostic Imaging

A tentative diagnosis of spinal neoplasia is typically based on signalment, history, clinical signs, and results of spinal imaging. In cases of vertebral neoplasia, bony lysis with loss of cortical outlines is often seen on imaging of affected vertebrae, with or without evidence of bony proliferation (Fig. 40.60). In most soft tissue spinal neoplasms, plain radiographs of the spine are normal. Myelography, CT, and MRI are usually helpful in diagnosis of spinal tumors and in therapeutic planning. An intramedullary myelographic pattern may be misleading in that an intradural/extramedullary mass with attendant cord swelling may cause an identical pattern on myelography or advanced imaging (e.g.,

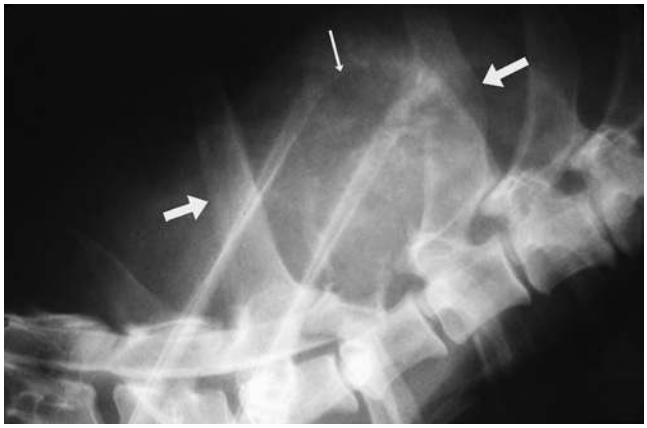

FIG. 40.60 Lateral myelogram of the cervical spine of a dog with a tumor of the T1 spinous process and dorsal lamina. Note the spinous processes of C7 and T2 *(large arrows)* and the absence of the spinous process of T1 *(small arrow)*. Profound spinal cord compression is illustrated by the inability of contrast to move distal to the level of T1.

CT, MRI). Intradural/extramedullary spinal tumors will occasionally infiltrate the spinal cord parenchyma (mixed compartment mass), and this may contribute to the development of an intramedullary imaging pattern. It is important to realize that both meningiomas and MNSTs tend to be associated with an intradural extramedullary pattern. In addition, both tumors appear to have a predilection for the cervical spinal cord. In some cases of MNST, an enlarged intervertebral foramen evident on radiographs, CT, or MRI, or an enlarged nerve root identifiable with CT or MRI may help in distinguishing a tumor as an MNST rather than a meningioma. Absence of such distinguishing imaging results, however, does not rule out the possibility of MNST. Definitive diagnosis of spinal tumors in all cases requires histopathologic evaluation of affected tissue. This is not usually feasible without surgical intervention. However, fluoroscopic- or CT-guided needle biopsy may provide a diagnosis in some cases.

Laboratory Findings

Results of laboratory analyses are usually normal, but hyperglobulinemia and proteinuria may be evident in cases of myeloma. Most cats with spinal lymphosarcoma are feline leukemia virus positive, have leukemic bone marrow, and have multicentric neoplasia. With the possible exception of spinal lymphosarcoma, CSF evaluation rarely reveals neoplastic cells but may reveal increased protein levels, with or without elevated cell counts (more likely with tumors with meningeal involvement).

DIFFERENTIAL DIAGNOSIS

Other disorders that cause progressive cervical myelopathy include type II disc protrusion, syringomyelia, and CCSM. Because some cervical spinal cord tumors may have more rapid onset and progression of clinical signs, type I disc extrusions, CJAs, and infectious/inflammatory disorders need to be on the differential diagnosis list.

MEDICAL MANAGEMENT

As with brain tumors (see Chapter 39), therapy for dogs and cats with spinal tumors can be divided into supportive and definitive treatments. Supportive therapies are directed against secondary sequelae of the spinal tumor (e.g., cord edema, pain), whereas definitive therapies are aimed at elimination of neoplastic tissue. Supportive therapy consists of antiinflammatory doses of glucocorticoids (e.g., prednisolone, 0.5 mg/kg PO, every 12 hours), which can be increased or decreased as needed, with or without additional pain-relieving drugs (e.g., narcotics). Definitive medical therapy for spinal tumors, similar to brain tumor medical definitive therapy, consists primarily of megavoltage radiation therapy and oral chemotherapy. Chemotherapy is indicated for lymphosarcoma, myeloma, meningioma, and glioma.

SURGICAL TREATMENT

Preoperative Management

Preoperative management of the patient undergoing cervical spinal surgery is discussed on p. 1366.

Anesthesia

See p. 1366 for anesthetic management of the cervical spinal patient. In addition, see Table 32.1 for anesthetic considerations in the stable orthopedic patient.

Surgical Anatomy

See p. 1366 for pertinent surgical anatomy of the cervical spine.

Positioning

Patient positioning for the dorsal approach to the cervical spine is discussed on p. 1370. Most cervical spinal tumor removals will be performed from a dorsal approach. On occasion, partial or complete vertebral body removal with stabilization may be attempted for vertebral masses. This technique requires a ventral approach (see p. 1367).

SURGICAL TECHNIQUE

Ventral and dorsal approaches to the cervical spine are described on pp. 1367 and 1370, respectively. Tumors amenable to surgical removal are typically extradural or intradural/extramedullary in location, without invasion into vertebral bodies. Intradural tumors require a durotomy to be performed (see p. 1396). Some intramedullary tumors may have distinct borders and can be removed via myelotomy (incision through a thin layer of spinal cord parenchyma overlying the tumor).

SUTURE MATERIALS AND SPECIAL INSTRUMENTS

In addition to standard instrumentation for spinal surgery, instruments such as lens loops, Bishop-Harmon forceps, and tenotomy scissors are often helpful in spinal tumor removal. A Cavitron ultrasonic aspirator may also be useful for removal of soft tissue spinal cord masses. In situations requiring extensive removal of surrounding bone (e.g., articular processes, vertebral body) with potential creation of instability, the surgeon should have access to necessary materials for stabilization procedures (e.g., pins, screws, locking plates, PMMA).

COMPLICATIONS

Complications associated with cervical spinal surgery are discussed on p. 1375. In addition to these complications, implant failure and infection are potential complications of stabilization procedures.

PROGNOSIS

The prognosis for dogs and cats with spinal neoplasia treated with supportive therapy alone is poor. Although data are lacking, these patients will likely be euthanized because of progressive spinal cord dysfunction within several weeks to several months of diagnosis, depending on the tumor type. For most canine and feline spinal tumors, meaningful prognostic information based on large numbers of cases in which definitive therapy was pursued is lacking. With the exception of lymphosarcoma, absence of prognostic information pertaining to feline spinal neoplasia is notable. In one report, prognostic data concerning nonlymphoid spinal neoplasia in 11 cats were described. Several cats experienced prolonged remissions following surgical intervention, including one cat with osteosarcoma, one with chondrosarcoma, one with an MNST, and one with meningioma, with survival times of approximately 57 months, 12 months, 73 months, and 47 months, respectively. The median survival time for four additional cats with meningioma was approximately 6 months after surgery.[32] In another report of 26 cats with nonlymphoid spinal tumors

treated surgically, the median survival time for benign tumors (e.g., meningioma) was 518 days, and for malignant tumors (e.g., osteosarcoma) the median survival time was 110.5 days.[33] Although based on a small number of cases, nonlymphoid spinal neoplasia may often be associated with a favorable prognosis in cats treated surgically. Evidence suggests that osteosarcomas may be less aggressive in cats than in dogs. The prognosis for most cases of vertebral neoplasia in dogs (e.g., osteosarcoma, chondrosarcoma) is considered poor. Surgical decompression may provide some temporary relief of clinical signs. However, vertebral neoplasms often cause such extensive bony destruction by the time of diagnosis that any further destabilization due to surgical intervention (e.g., laminectomy) may hasten the development of a pathologic fracture/luxation. Radiation therapy and chemotherapy are usually unsuccessful in the treatment of these tumors. In one report of dogs with vertebral tumors treated via various methods (e.g., surgery, radiation therapy, chemotherapy), the median survival time was 135 days. Sustained remissions (>1 year) are likely in patients with plasma cell tumors (myeloma) of the vertebrae that are treated with chemotherapy.[34] Although chemotherapy or radiation therapy is the recommended definitive therapy for spinal lymphoma, most feline and canine patients will be euthanized within 3 months because of progressive or recurrent disease, despite therapy. Limited available information on spinal meningiomas suggests that remission times exceeding 6 months are likely with surgical therapy alone; adjunctive radiation therapy is likely to extend remission times for this tumor to 12 months or longer.

The prognosis for surgical removal/debulking of canine spinal MNSTs appears to be poor. Median postoperative survival is approximately 5 to 6 months, with a disease-free interval of only approximately 1 month. The efficacy/inefficacy of postoperative radiation therapy for spinal MNSTs has not yet been established for dogs or cats. Intramedullary spinal neoplasia is uncommon. The prognosis for dogs and cats with these tumors is considered poor, although definitive therapy has not been thoroughly described. Several reports have described surgical removal of lipomatous spinal cord masses in dogs. Although the overall success rate of surgery appears to be favorable, even with infiltrative lipomas and liposarcomas, postoperative radiation therapy may be advisable with these latter two tumor types to achieve good long-term results.

SPINAL TRAUMA

DEFINITIONS

Similar to brain injury, spinal trauma is conceptually divided into primary injury and secondary injury. **Primary injury** refers to that which occurs immediately after impact, whereas **secondary injury** describes the ensuing biochemical processes that potentiate further spinal cord damage. Disruption of supportive structures of the spinal column can occur as a true **fracture** if the vertebrae are damaged, as **luxation** (displacement from normal spinal alignment) without fracture if the damage occurs to soft tissues alone, or as a combination of fracture and luxation. **Concussive** spinal cord injury describes injury to the spinal parenchyma sustained from blunt force trauma that does not necessarily require fracture/luxation of supporting bony and ligamentous structures.

GENERAL CONSIDERATIONS AND CLINICALLY RELEVANT PATHOPHYSIOLOGY

Fracture/luxation of the cervical spine in dogs and cats is most commonly the result of vehicular trauma. Other causes include projectile injuries (e.g., gunshot), bite wounds (e.g., "big dog–little dog" altercations), and running head-first into a stationary object. Pathologic fracture/luxation may occur with minor trauma in some cases owing to weakened bone (e.g., vertebral neoplasia) or abnormal anatomy (e.g., AA instability). Fracture luxation of the cervical spine occurs less commonly than in the thoracolumbar spine, and the C2 vertebra and the C1–C2 articulation represent the most common areas for fracture/luxation. This is thought to be due to the concentration of stresses at the level of the C2 vertebra caused by cranial and caudal anatomic attachments (Fig. 40.61). Following the initial traumatic event, further impact injury to the spinal cord can occur if unstable segments continue to move and repetitively traumatize the spinal cord parenchyma in the damaged area of the spine.

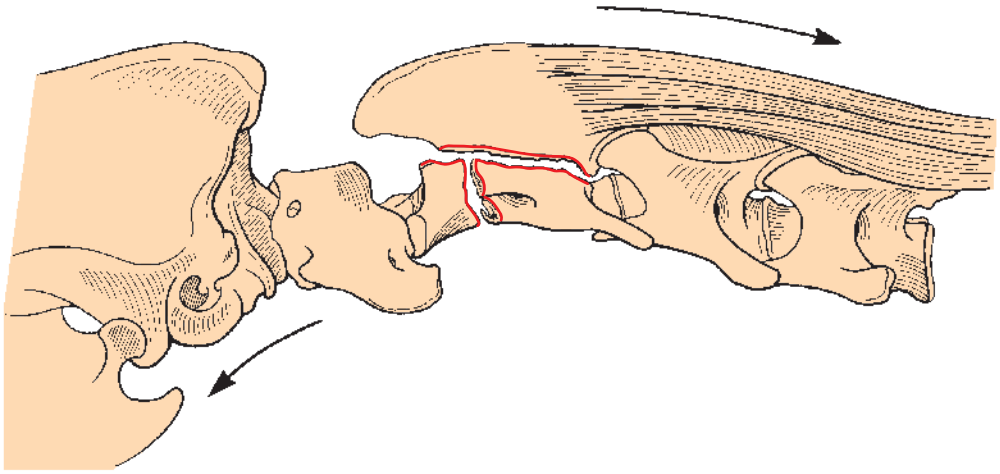

FIG. 40.61 A static-kinetic relationship is produced between the cervicocranium and the lower cervical spine; the axis is the point of stress concentration resulting in fracture/luxation.

DIAGNOSIS

Clinical Presentation

Signalment

Although most spinal cord injuries occur in younger animals (<5 years old), no age, breed, or sex predilection for spinal trauma has been noted.

History

The history of trauma is often definitive, in that the incident (e.g., hit by car) was actually witnessed. In some cases, spinal trauma is inferred when an animal is found with neurologic deficits consistent with cervical myelopathy and other external evidence of trauma (e.g., abrasions, bite wounds). Most patients will present to the hospital soon after trauma with a brief history of neck pain and variable levels of proprioceptive and motor deficits in all four limbs.

Physical Examination Findings

As with brain injury patients, dogs and cats that have experienced traumatic spinal injury often present to the hospital in a state of shock. The basic tenets of shock management need to be followed before an in-depth assessment of neurologic status is performed. However, when the clinician suspects cervical spinal trauma, it is imperative to keep the patient as immobile as possible until obvious instability is ruled out or corrected. It is important to perform as thorough a neurologic examination as possible (see Chapter 38), but certain aspects of the examination (e.g., hopping, wheelbarrowing) should be left out until more is known about the stability of the cervical spinal column. Gentle palpation of the cervical spine may help localize the region of injury.

Diagnostic Imaging

Several methods of imaging the spinal column of the traumatized patient are known; radiographs are the most commonly performed on an emergency basis. It is important to obtain imaging of the entire spinal column because multiple fractures or luxations may be present. Radiographs may be taken in the awake patient, but subtle lesions may be difficult to evaluate in some animals if they are moving excessively. Sedation or anesthesia allows more detailed imaging but removes the patient's ability to protect the fracture/luxation site by contracting surrounding musculature. If possible, we prefer to obtain lateral radiographs of the entire spine in the conscious patient (after addressing any systemic concerns associated with trauma) to screen for overt fractures/luxations that are present. Following this, further radiographic views or CT images of the spine may be obtained. We prefer CT of the entire spine in these patients for several reasons. With current CT machines, scans are extremely rapid and the entire spine of a large dog can be completed under sedation within minutes. Patient repositioning is not required, and images can be reconstructed in multiple planes and three-dimensionally (Fig. 40.62). CT is more reliable than radiographs in identifying both the number and the extent of fractures/luxations. In addition, measurements for implants can be easily and accurately made from CT images. In the anesthetized patient, myelography can be performed as an adjunct to radiographs or in conjunction with CT (CT/myelogram). Use of contrast with radiography or CT in cases of spinal trauma is a matter of clinician preference. In our experience, contrast in such cases rarely provides much useful clinical information. MRI can also be used to assess cervical spinal cord trauma; it is our opinion that, although MRI may provide superior soft tissue detail in cervical spinal cord trauma, CT is generally preferable to MRI for assessing spinal injury in such cases. Classification of a cervical fracture/luxation as stable or unstable can be obvious in some cases but is more subjective in others. The three-compartment model (Fig. 40.63) is often used to assess the likelihood of instability, with disruption of two or three of the compartments constituting evidence of instability. This model is a potentially useful guideline but should not be viewed as an absolute determinant. Other factors, such as patient demeanor (i.e., a very active and hyperexcitable patient may not do well with conservative fracture management), location of fracture lines in reference to tension and compression forces, and spinal cord impingement by bone fragments or disc material, need to be considered when decisions concerning medical versus surgical management are made.

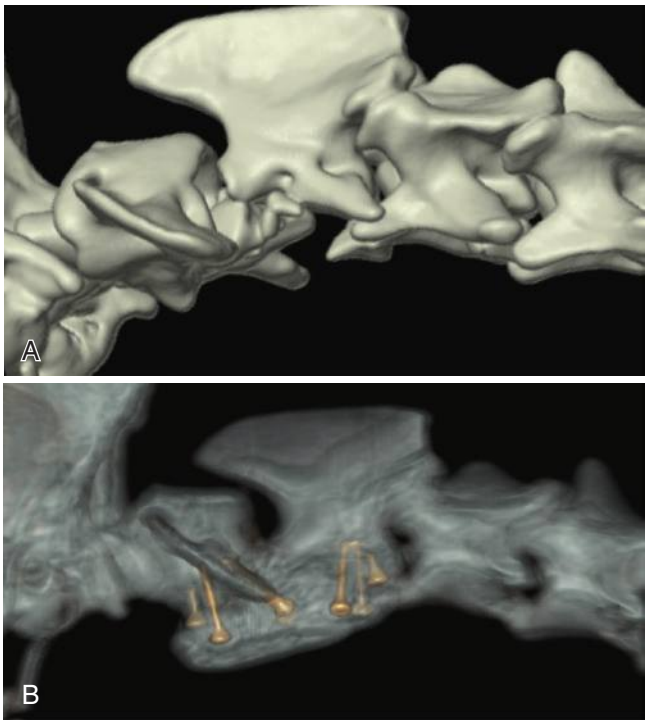

FIG. 40.62 Three-dimensional reconstructed computed tomography image of a dog with a C2 vertebral body fracture (A) before and (B) after surgical reduction and fixation with cortical screws and polymethylmethacrylate.

Laboratory Findings

Results of laboratory analyses (e.g., CBC, biochemical profile) are typically unremarkable in patients with cervical spinal trauma, or are reflective of the experience of a traumatic event (e.g., stress leukogram).

DIFFERENTIAL DIAGNOSIS

In cases of cervical spinal trauma in which the traumatic event was witnessed or clear evidence of associated trauma is found, no other differential diagnoses need to be considered. In situations that involve relatively minor trauma, it is important to consider the possibility of a pathologic fracture. Animals that are found by their owners with sudden onset of cervical myelopathy with no known traumatic event may have experienced ischemic insult to the spine (see p. 1448). In these cases, the absence of overt spinal hyperesthesia is a common historical and clinical feature.

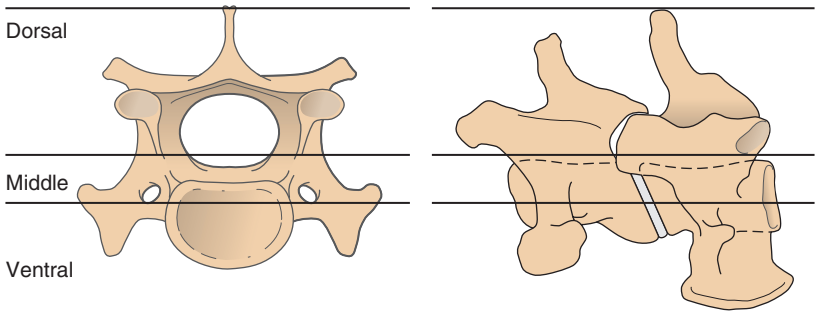

FIG. 40.63 Three-compartment model for evaluating the stability of a vertebral fracture/luxation.

TABLE 40.2 Anatomic Variations of the Atlas and Axis Important to Surgical Repair of Atlantoaxial Instability

Vertebrae	Anatomy	Surgical Significance
C–atlas	Thin dorsal arch (laminae); no dorsal spinous process No vertebral body, just thin ventral fovea Ventrolateral diarthrodial joints Prominent ventral tubercle Prominent wings	Poor implant-holding power dorsally Poor implant-holding power ventrally Good purchase for implants ventrally; used to evaluate anatomic reduction Landmark for surgical localization Moderate implant-holding power dorsally and ventrally
C2-axis	Prominent dorsal spinous process Thin central vertebral body Prominent cranial articular processes Prominent caudal vertebral body Dens	Moderate implant-holding power dorsally, patient age and size dependent; landmark for surgical localization Poor implant-holding power ventrally Good purchase for implants ventrally; used to evaluate anatomic reduction Good ventral purchase for implants May fracture or displace into vertebral canal
C–C2	Bilateral ventrolateral diarthrodial joints Dorsal atlantoaxial ligament	Good purchase for implants ventrally; used to evaluate anatomic reduction Moderate purchase of implants used to replace the ligament

MEDICAL MANAGEMENT

Providing treatment for shock and immobilizing the spine are the initial goals of medical therapy. In addition, analgesics for pain should be administered as needed. In patients that are deemed viable candidates for nonsurgical management of cervical spinal trauma, strict cage confinement with or without a neck brace is typically indicated. Although many factors go into the decision to medically manage a cervical spine trauma case, this mode of management is usually chosen for ambulatory patients with minimal displacement of vertebrae or fracture segments. It is also chosen for patients with no evidence of fracture/luxation or spinal cord compression, even if nonambulatory (e.g., suspected concussive cord injury). Neurologic deterioration during medical therapy is an indication to pursue surgical stabilization, with or without decompression.

Specific medical therapeutic interventions to combat secondary spinal injury processes are lacking. Glucocorticoid therapy has not been shown to improve outcome in clinical spinal cord injury, and excessive use of glucocorticoids in such cases can have major detrimental effects (e.g., gastrointestinal ulceration/perforation). Evidence has shown that intravenous PEG therapy is not beneficial for victims of spinal cord injury (see p. 1366).[1]

SURGICAL TREATMENT

Surgical treatment is provided with two objectives: stabilization and decompression. The most pressing goal is to provide stabilization, and decompression should generally not be performed in spinal fracture/luxation scenarios without some level of stabilization being provided. Decompression is performed dorsally (for spinal cord parenchyma) or dorsolaterally (nerve root impingement), and stabilization is most commonly performed ventrally. Dorsal stabilization can be performed in the cervical region, but the bone available for implants is sparse. Cranial cervical vertebral bodies have substantially less bone available for ventral implants than caudal vertebrae. Anatomic considerations and their impact on implant selection are summarized in Table 40.2. In our experience, presurgical CT measurements are invaluable in selection of implants for individual patients.

Preoperative Management

Preoperative management of the patient undergoing cervical spinal surgery is discussed on p. 1366. For trauma patients, blood should be available for transfusion. Hemorrhage from lacerated venous sinuses can occur at the time of trauma or during fracture/luxation reduction.

Anesthesia

See p. 1366 for anesthetic management of the cervical spinal patient. In addition, see Table 32.2 for anesthetic considerations for the acute trauma patient.

Surgical Anatomy

See p. 1366 for pertinent surgical anatomy of the cervical spine.

Positioning

Patient positioning for the ventral approach to the cervical spine is provided on p. 1367. Positioning for the dorsal approach to the cervical spine is described on p. 1370.

SURGICAL TECHNIQUE

The surgical technique or techniques used will depend on several factors, including the location of the injury, the type and shape of the injury, whether or not decompression is needed, and the experience/preference of the surgeon. Dorsal and ventral approaches to the cervical spine are described on pp. 1370 and 1367, respectively. Types of implants are described in other sections of this chapter (CJA, CCSM) and include pins/screws and PMMA (Fig. 40.64), spinal plates (Fig. 40.65), and articular process (facet) screws (Fig. 40.66). In some cases, ventral stabilization is required in addition to dorsal or dorsolateral decompression. In these situations, ventral stabilization is performed, followed by dorsal or dorsolateral decompression. Dorsal stabilization can be added as well but should be considered as adjunctive rather than primary stabilization. From the ventral approach, fracture/reduction stabilization can often be facilitated by the use of ASIF small fragment reduction forceps.

SUTURE MATERIALS AND SPECIAL INSTRUMENTS

In addition to standard instrumentation required for cervical spine surgery, cancellous and cortical bone screws, spinal plates, pins (positive-profile thread), PMMA, and ASIF small fragment reduction forceps should be available for cervical spinal stabilization.

POSTOPERATIVE CARE AND ASSESSMENT

Postoperative evaluation and management of cervical spinal trauma patients are very similar to those for dogs and cats with other spinal disorders. Particular attention should be paid to managing pain and limiting excessive movement. Although stabilization procedures should leave the fracture/luxation "stable at the table," all fixations are subjected to repetitive mechanical forces that may threaten implant integrity in the early stages of healing.

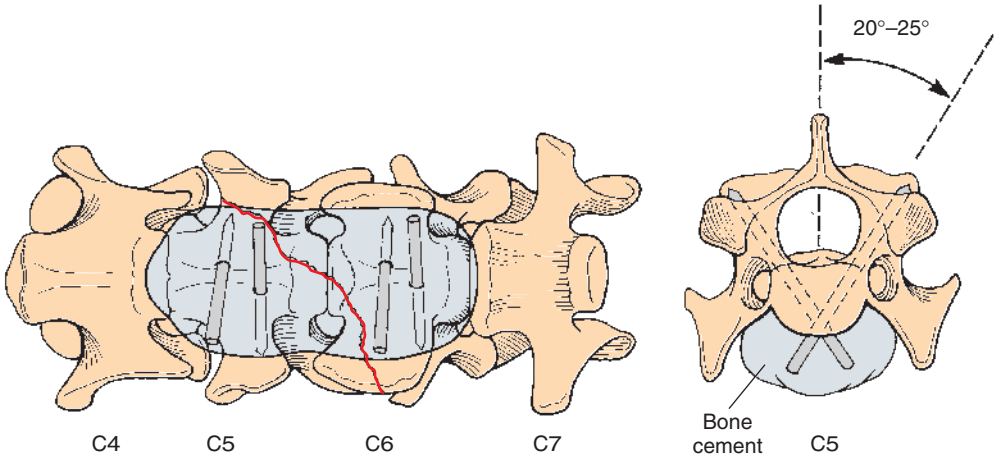

FIG. 40.64 Ventral stabilization of C3–C7 fracture/luxation using Steinmann pins and polymethylmethacrylate in the ventral bodies. Note that the pins are angled away from the vertebral canal.

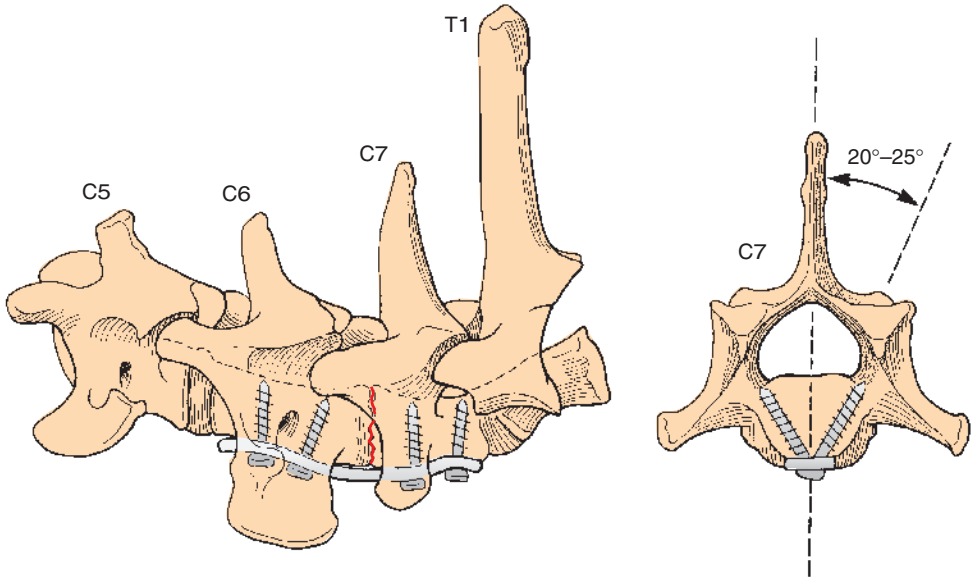

FIG. 40.65 Ventral stabilization of C3–C7 fracture/luxation using plastic spinal plates on the ventral vertebral bodies. Note that the screws are angled away from the vertebral canal.

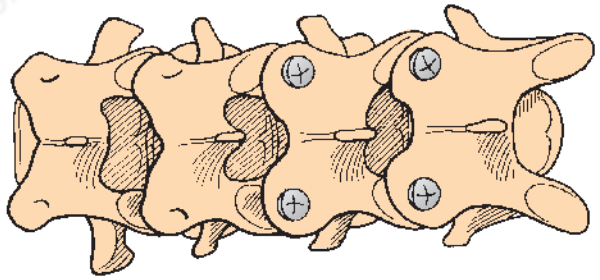

FIG. 40.66 Dorsal stabilization of C6–C7 fracture/luxation using articular facet screws.

PROGNOSIS

In general, the prognosis for most medically and surgically treated cervical spinal trauma patients is favorable. For surgically managed patients, prognosis is highly dependent on appropriate preoperative and postoperative care, in addition to the specific mode of surgical treatment applied.

Surgery of the Thoracolumbar Spine

GENERAL PRINCIPLES AND TECHNIQUES

DEFINITIONS

Weakness of both pelvic limbs due to a thoracolumbar myelopathy is **paraparesis.** The term used to describe loss of voluntary motor ability to both pelvic limbs is **paraplegia.** The most commonly performed surgical approaches to the thoracolumbar spine are **hemilaminectomy** and **dorsal laminectomy.** Hemilaminectomy is unilateral removal of the lamina, articular processes (facets), and part of the pedicle. Dorsal laminectomy is removal of the dorsal lamina bilaterally, including removal of the dorsal spinous process. Portions or all of the articular processes can be removed during a dorsal laminectomy, depending on the desired exposure and risks of causing instability. Hemilaminectomy and dorsal laminectomy can be combined to create a **dorsolateral hemilaminectomy.** A scaled down version of hemilaminectomy that involves removal of portions of the pedicle cranial and caudal to the intervertebral foramen with preservation of the articular processes is called **pediculectomy;** this procedure has limited clinical application and will not be discussed in detail. **Partial lateral corpectomy** is removal of part of the vertebral body ventral to the vertebral canal; the main indication for this procedure is removal of chronic type II disc protrusions.

GENERAL CONSIDERATIONS

As with cervical myelopathies, a broad range of clinical severity is associated with thoracolumbar myelopathies in dogs and cats. In contrast to cervical myelopathies, inability to walk on the pelvic limbs (nonambulatory paraparesis, paraplegia) is the most common clinical scenario in thoracolumbar myelopathies, rather than spinal hyperpathia with minimal to no neurologic deficits. It is much more common for dogs and cats to experience upper motor neuron (UMN) bladder dysfunction with thoracolumbar myelopathies than with cervical myelopathies. In general, most patients that retain or regain (postsurgically) voluntary motor ability to the pelvic limbs will have voluntary control of micturition. Bladder management is a vital component of patient care in treatment for thoracolumbar myelopathies.

Preoperative Management

Preoperative management of the patient with thoracolumbar myelopathy is similar to that described for the patient with cervical myelopathy (see Chapter 40). If instability is known or suspected (e.g., spinal trauma), the patient should be immobilized on a rigid surface, and excessive motion to the thoracolumbar spine should be prevented. A thorough neurologic examination is essential, as is a complete history of the patient's neurologic status before hospital admission. In paraplegic patients, it is imperative to accurately assess the ability of the dog or cat to perceive noxious stimuli applied to the toes of the pelvic limbs. Absence of deep pain perception (DPP) (see p. 1336) is a negative prognostic indicator, especially in trauma cases. The length of time that DPP has been absent is suspected to be inversely related to prognosis, emphasizing the importance of an accurate history. Assessment of neurologic dysfunction as UMN or lower motor neuron in nature is important for localization purposes but does not affect prognosis. Similarly, the presence of Schiff-Sherrington posture (see p. 1330) is helpful in lesion localization but is not a prognostic indicator.

Anesthetic Considerations

Anesthetic management of the patient with thoracolumbar myelopathy is similar to that described for the patient with cervical myelopathy (see p. 1366). In addition, see Tables 32.1 and 32.2 for anesthetic considerations in orthopedic patients.

Antibiotics

Intravenous antibiotics (e.g., cefazolin, 22 mg/kg) should be administered perioperatively (30 minutes before initiation of surgery and every 90–120 minutes thereafter during surgery) and discontinued after surgery or within 24 hours.

Surgical Anatomy

There are 13 thoracic vertebrae and seven lumbar vertebrae. All of these vertebrae have similar components (vertebral body, lamina, pedicle, articular processes, transverse processes, dorsal spinous process), but these components differ substantially in size and shape along the vertebral column (Figs. 41.1 and 41.2). Of particular importance to the surgeon are the differences between the first 10 and the last three thoracic vertebrae and their articulations with each other. The articular processes from T1 through T10 are oriented dorsoventrally like the cervical articular processes (from C2–C3 caudally). Unlike the cervical articular processes, however, these thoracic articular processes do not present an obvious distinct anatomic boundary between what is articular process and what is lamina. From the T10–T11 articulation caudally, the joint spaces of the articular processes are located in a sagittal plane, with the cranial articular process joint surface facing medially and the caudal articular process joint surface facing laterally. The tubercles of the ribs articulate with the transverse processes of the thoracic vertebrae of the same number. The dorsal spinous processes of the thoracic vertebrae decrease in height from cranial to caudal and change from a caudal to a cranial orientation typically after the 11th

ABSTRACT

The thoracolumbar region is the most commonly operated area of the spine in small animal practice, principally for type I disk extrusions. Detailed knowledge of the surgical approaches to the thoracolumbar spinal cord, particularly hemilaminectomy, is requisite for neurosurgeons. Although less commonly encountered in clinical practice, surgery is sometimes required in the cranial thoracic region (e.g., for congenital kyphotic vertebral malformations); surgical intervention in this area of the vertebral column is technically demanding. Other topics that neurosurgeons should be familiar with are thoracolumbar neoplasia and fracture/luxations, including implant placement.

(anticlinal) thoracic vertebra, the dorsal spinous process of which is oriented dorsally. From midthoracic to approximately the fifth or sixth lumbar vertebra, there is a distinct accessory process lateral to and at the ventral base of the cranial articular process. From the T11–T12 space caudally, the intervertebral foramen is ventral to the accessory process; from T10–T11 cranially, the

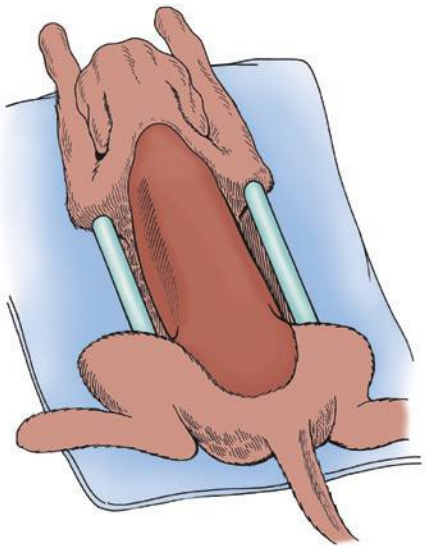

FIG. 41.3 Positioning a dog for a dorsal approach to the cranial and midthoracic spine.

intervertebral foramen is located between the accessory process and articular processes. At the T11–T12 articulation, there is typically a space between the accessory and articular processes; caudal to this articulation, the accessory process is flush with the articular processes. The lumbar vertebrae have large distinctive transverse processes that are oriented cranially and slightly ventrolaterally. The "elbow" of these processes (the cranial aspect of the base of the process near the junction with the pedicle) represents an important surgical landmark for implant placement. The dorsal spinous processes of the lumbar vertebrae are directed slightly cranially; they are largest in the midlumbar region. The dorsal spinous process of the seventh lumbar vertebra is palpably shorter than that of the sixth lumbar vertebra.

Large, paired venous sinuses (internal vertebral venous plexus) run longitudinally on the ventrolateral aspect of the vertebral canal. The thick dorsal longitudinal ligament is located on the ventral aspect of the vertebral canal. Nerve roots, branches of the venous sinuses, and radicular arteries pass laterally through the intervertebral foramina.

STANDARD SURGICAL APPROACHES TO THE THORACOLUMBAR SPINE

DORSAL APPROACH TO THE CRANIAL AND MIDTHORACIC SPINE

The most common indications for the dorsal approach to this region of the thoracic spine include removal of tumors and stabilization/decompression of congenital vertebral anomalies (e.g., "hemivertebrae"). In the latter scenario, it is essential to understand that stabilization of the abnormal region is mandatory. *Position the patient in sternal recumbency with the thoracic limbs pulled cranially (Fig. 41.3) and close to the body. Alternatively, cross the thoracic limbs.* The goal is to abduct the dorsal scapulae so that they do not interfere with the approach.

Make a dorsal midline incision from the caudal cervical to the caudal thoracic region (depending on the specific region of interest and the specific procedure to be performed). Incise the subcutaneous

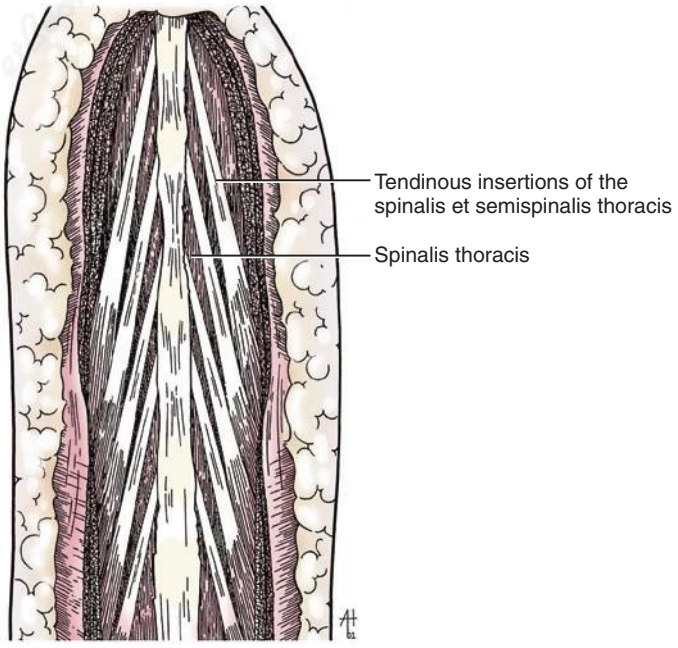

FIG. 41.4 Approach to the cranial and midthoracic spine after retraction of trapezius and rhomboideus muscles. Exposed are the tendons of the spinalis et semispinalis thoracis, and the spinalis thoracis.

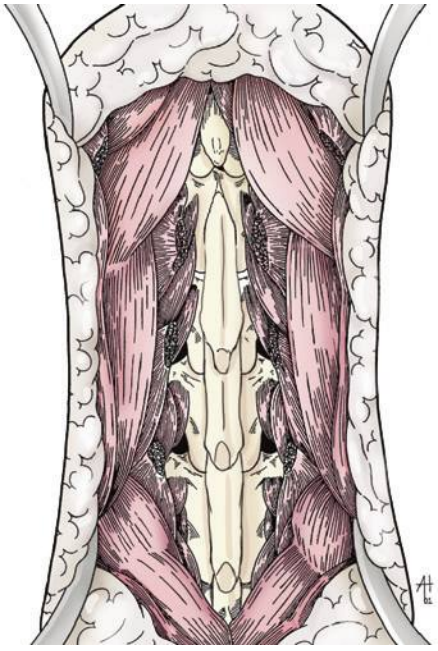

FIG. 41.5 Approach to the cranial and midthoracic spine after elevation of the multifidus musculature and when performing a hemilaminectomy with undercutting of the dorsal spinous process.

tissue to expose the median raphe. Incise the raphe on either side of the transverse processes, controlling hemorrhage with monopolar or bipolar cautery. Retract the trapezius and underlying rhomboideus muscles laterally to expose the serratus dorsalis musculature. Incise the fascia of this musculature along either side of the median raphe close to the dorsal spinous processes, and reflect these muscles laterally to expose the spinalis et semispinalis thoracis musculature and associated tendinous insertions on the dorsal spinous processes (Fig. 41.4). Sharply incise the attachments of these muscles to the dorsolateral aspects of the dorsal spinous processes bilaterally, and then elevate these and deeper epaxial muscles off the lateral aspects of the dorsal spinous processes using Freer elevators (small dogs and cats) or Army-Navy osteotomes. Insert Gelpi retractors at the caudal and cranial aspects of the incision at this time, and remove epaxial musculature from the articular processes to the level of the rib tubercle (if indicated) using a combination of sharp and blunt dissection and bipolar cautery. Several options are available for performing decompression at this point. In our opinion, the dorsal spinous processes should be preserved and a full dorsal laminectomy avoided if at all possible. In this region of the spine, the articular facets probably contribute more to spinal stability than in other regions of the spine, and these facets are difficult to distinguish from laminae at their medial aspects. *Perform a hemilaminectomy using a high-speed air drill, taking care to avoid the intervertebral foramen while drilling. Drill through outer cortical and inner cancellous bone as described for dorsal laminectomy of the cervical region (see p. 1370), then carefully drill the inner cortical layer until it is thin and flaky (like phyllo dough).* In small-breed dogs and cats, the bone in this region of the spine may not have an obvious cancellous layer. *Once the inner cortical layer is thin enough, remove it with a probe (e.g., Gross ear hook and spoon) or fine-tipped Lempert rongeurs. If necessary, undercut the lamina beneath the dorsal spinous process to midline or slightly past midline for increased exposure (Fig. 41.5). If a complete dorsal laminectomy is performed, stabilize the spine. Close the incision routinely.*

DORSAL APPROACH TO THE THORACOLUMBAR SPINE

This approach is the most frequently used in veterinary spinal surgery. It provides access to dorsal, lateral, and ventrolateral aspects of the vertebrae and spinal cord. Dorsal laminectomy, hemilaminectomy, and combinations of these two procedures can be performed via this approach. Indications for this approach include removal of compressive masses (e.g., disc material, hemorrhage, neoplasia, fracture fragments) and application of implants. *Position the patient in sternal recumbency with the thoracic and pelvic limbs in a flexed position (Fig. 41.6). Create a dorsal midline incision approximately three vertebral lengths cranial and caudal to the region of interest. Incise through subcutaneous fat and fascia to reveal the thoracolumbar fascia. Incise the thoracolumbar fascia (unilaterally for a hemilaminectomy, bilaterally for a dorsal laminectomy) just lateral to a dorsal spinous process at the caudal aspect of the incision, and continue the fascial incision cranially using Mayo scissors. Angle the scissor blades away from you to avoid a flap of fascia that will hang into the approach. Use Freer elevators or Army-Navy osteotomes to subperiosteally elevate the multifidus musculature off the lateral aspects of the dorsal spinous processes (Fig. 41.7). Remove any remaining muscular attachments with Metzenbaum scissors. Working caudally to cranially, place a Freer elevator or a small osteotome beneath the multifidus muscle caudal to the articular processes (facets), and pull the muscle dorsally and cranially over the facets, elevating the*

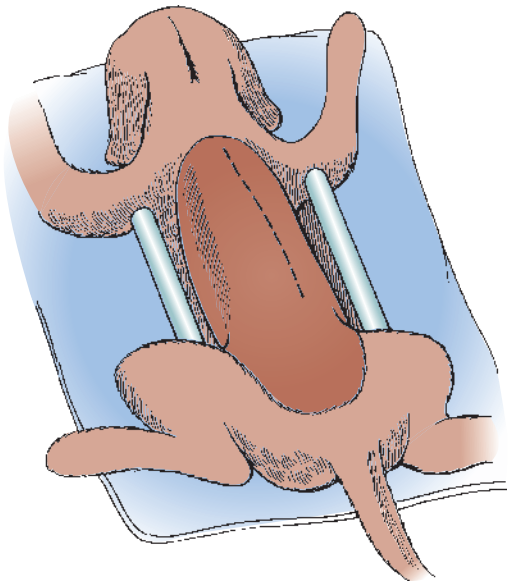

FIG. 41.6 Positioning the patient for a dorsal approach to the thoracolumbar spine.

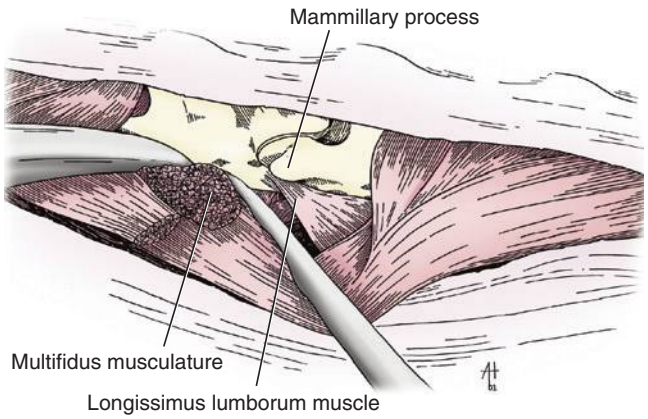

FIG. 41.8 Use of periosteal elevators to remove the attachments of the multifidus musculature to the mammillary process on the cranial articular process (facet). The tendinous attachment of the longissimus lumborum muscle to the accessory process is identified.

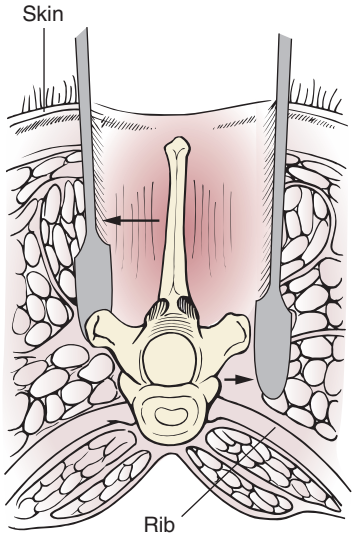

FIG. 41.7 Elevation of the multifidus musculature off the dorsal spinous processes.

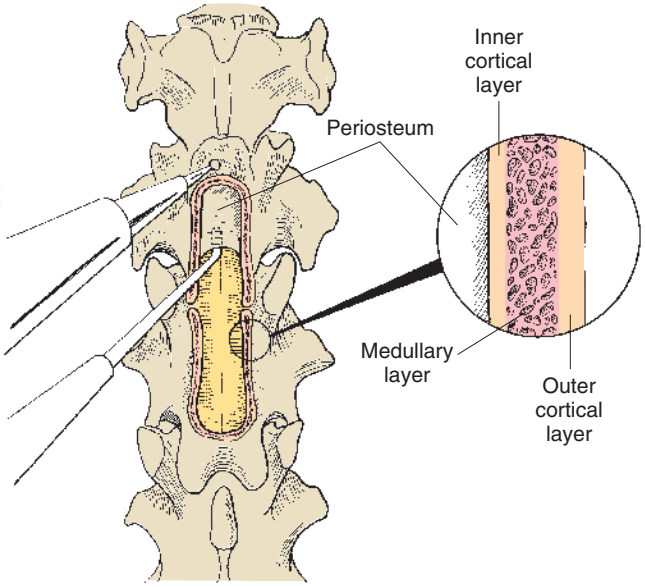

FIG. 41.9 For dorsal laminectomy, carefully drill through outer cortical and cancellous medullary bone layers to reach inner cortical bone. Use a paintbrush stroke to drill this last layer until periosteum is reached. Use a small probe and/or the tips of Lempert rongeurs to remove this final layer.

muscle attachments off the facets with another elevator or osteotome. At the cranial aspect of the facets, locate the white fibrous attachment of the multifidus musculature to the mammillary process (on the cranial articular facet), and remove this attachment with Mayo scissors and/or bipolar cautery (Fig. 41.8). Repeat this process for the remainder of the facets to be uncovered. Place Gelpi retractors in the cranial and caudal aspects of the incision. When performing a hemilaminectomy, place one end of the Gelpi retractor in the interspinous space, the other beneath the multifidus musculature (Videos 41.1 to 41.9). When performing a dorsal laminectomy place both ends of the Gelpi retractors beneath the multifidus musculature. If the dissection already described has been performed bilaterally, exposure is sufficient for performing a dorsal laminectomy. *To perform a dorsal laminectomy, remove the dorsal spinous processes over the intended laminectomy site using bone cutters or double-action rongeurs. Use a high-speed air drill to remove the outer cortical, inner cancellous, and inner cortical bone layers as previously described (Fig. 41.9). To perform a hemilaminectomy, locate the tendons of insertion of the longissimus lumborum musculature, and transect these tendons from their insertions on the accessory process with sharp Metzenbaum scissors or bipolar cautery (Fig. 41.10).* Spinal nerves and blood vessels are located beneath these tendons and should be avoided. *Remove portions of the articular processes using a Lempert or Ruskin rongeur*

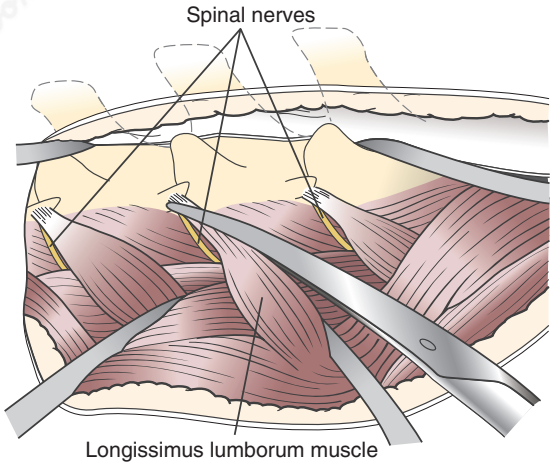

FIG. 41.10 Resection of the tendons of the longissimus lumborum muscles from the accessory processes to improve exposure for hemilaminectomy. The spinal nerve is located beneath the tendon of the longissimus muscle.

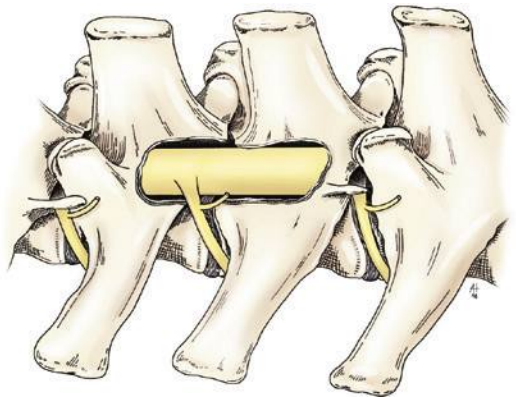

FIG. 41.11 Diagrammatic representation showing the location and extent of a typical left-sided hemilaminectomy.

to make this region more level with the pedicle. Use a high-speed air drill to remove the pedicle, the articular processes, and part of the lamina (undercut the dorsal spinous process).

The bone transition of outer cortical–inner cancellous–inner cortical is similar to that described for dorsal laminectomy. Because of the curvilinear shape of the area to be removed, the dorsal and ventral aspects of the hemilaminectomy are thicker than the middle section. Concentrating on the middle section will likely result in the creation of a narrow hemilaminectomy defect. We prefer to create a wide, rectangular defect (Fig. 41.11) to provide adequate decompression and to allow for ready removal of compressive tissue. We also prefer to leave the accessory process intact until the hemilaminectomy is completed (decreased chance of hemorrhage); this process is easily "snipped" off using the tips of Lempert rongeurs, if indicated. The venous sinuses are likely to be visualized with this approach. *If venous sinus hemorrhage occurs, control the hemorrhage with Surgicel or Gelfoam as described for cervical spinal surgery (see p. 1366).*

A miniaturized version of the hemilaminectomy, called a *pediculectomy* (Fig. 41.12), can also be performed via this approach. *Close the incision routinely.*

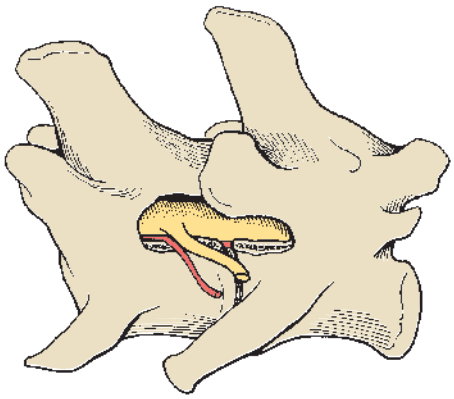

FIG. 41.12 Remove pedicular bone cranial and caudal to the intervertebral foramen during pediculectomy. Cranial and caudal articular processes (facets) are preserved.

LATERAL AND DORSOLATERAL APPROACHES TO THE THORACOLUMBAR SPINE

There are limited applications for these approaches to the spine, which include access to intervertebral discs for fenestration, exposure for pediculectomy, and exposure for lateral corpectomy. These approaches can be performed with the patient in sternal, oblique sternal, or lateral recumbency, depending on surgeon preference. *Create a skin incision lateral to the dorsal midline at approximately the levels of the rib heads and transverse processes (depending on the specific region to be exposed) for the lateral approach and at 1.0 to 2.0 cm lateral to the midline for the dorsolateral approach (Fig. 41.13). Incise through subcutaneous fat and fascia to reach the thoracolumbar fascia. Incise the thoracolumbar fascia to expose an underlying second layer of fat and the thoracolumbar musculature. For the lateral approach, identify and bluntly dissect between the fascicles of the iliocostalis lumborum muscles to expose the rib head or the transverse process (Fig. 41.14). Clear the musculature off the pedicle and disc space using a Freer elevator, and retract the iliocostalis lumborum fascicles with Gelpi retractors (Fig. 41.15). For the dorsolateral approach, bluntly separate between the longissimus lumborum and multifidus lumborum at the septum between these muscle masses (Fig. 41.16) in a craniomedial direction until the tendons of the longissimus muscles are revealed, inserting on the accessory processes. Elevate the musculature off of the intended region of exposure as described for the lateral approach, using Freer elevators. Close the incision routinely.*

HEALING OF THE SPINAL CORD

For healing of the spinal cord, see p. 1373.

SUTURE MATERIALS AND SPECIAL INSTRUMENTS

The neurosurgical instrumentation required for surgery of the thoracolumbar spine is essentially the same as that used for brain (p. 1345) and cervical spine surgery (p. 1374). For some thoracolumbar fracture/luxation scenarios, both basic plating equipment (see pp. 1016–1023) and specialized plates (e.g., string-of-pearl plates, Lubra plates, Auburn plates) may be required, depending on surgeon preference.

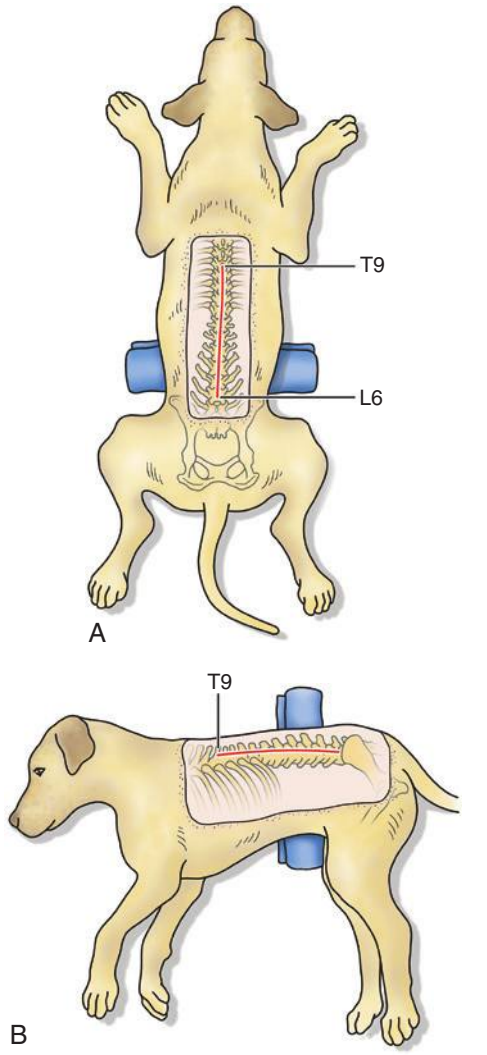

FIG. 41.13 Approximate level of skin incision for (A) dorsolateral and (B) lateral approaches to the thoracolumbar spine.

POSTOPERATIVE CARE AND ASSESSMENT

Postoperative care of the thoracolumbar surgical patient is similar to what is described for surgery of the cervical spine. Patients with thoracolumbar spinal cord disease are more likely to be nonambulatory than dogs with cervical lesions and more likely to have UMN urinary incontinence. Therefore physical therapy and attentive bladder management is commonly required for these patients. It is prudent to keep patients hospitalized until they are able to urinate on their own, as many owners have difficulty with bladder expression. The majority of dogs and cats with thoracolumbar spinal cord injuries who have voluntary pelvic limb motor function are able to urinate voluntarily. In patients with no DPP to the pelvic limbs, functional recovery is often prolonged or unlikely. In these scenarios, teaching pet owners about bladder management and principles of physical therapy is often necessary. A number of carts are available for patients who are expected to be nonambulatory paraparetic or paraplegic for extended periods of time.

COMPLICATIONS

Complications associated with thoracolumbar spine surgery are similar to those described for cervical spine surgery (see p. 1375). When working in the cranial to midthoracic spine, especially if near the rib heads, pneumothorax is a possible complication. Inadvertent damage to thoracic or lumbar nerve roots during surgery may lead to a transient visible bulge of a section of abdominal musculature on the operated side. Although uncommonly reported, very wide dorsal laminectomies may predispose to the development of a constrictive laminectomy "membrane" (scar tissue).

SPECIAL AGE CONSIDERATIONS

See p. 1375.

SPECIFIC DISEASES

THORACOLUMBAR DISC DISEASE

DEFINITIONS

As discussed with cervical disc disease (see p. 1375), thoracolumbar disc disease refers to degeneration of the nucleus pulposus (**Hansen type I,** or **type I** degeneration) or the annulus fibrosus (**Hansen type II,** or **type II** degeneration) and the clinical consequences of this degeneration. Type I degeneration is also called *chondroid degeneration,* and type II degeneration is called *fibroid degeneration.* Hydrated nucleus pulposus extrusion has been documented in the thoracolumbar region in dogs[1] but is more commonly reported in the cervical spine. Hydrated nucleus pulposus extrusion is discussed in more detail in Chapter 40.

GENERAL CONSIDERATIONS AND CLINICALLY RELEVANT PATHOPHYSIOLOGY

The pathophysiology of disc disease is discussed in Chapter 40 under cervical disc disease (p. 1375). Type I disc extrusions in dogs and cats (much less common) are usually ventral or ventrolateral (Fig. 41.17). Type I disc disease in the thoracolumbar region is more frequently encountered than cervical disc disease. Disc problems cranial to the T10–T11 disc space are uncommon, probably because of the stabilizing influence of the intercapital ligament (Fig. 41.18). This ligament passes over the dorsal annulus from rib head to rib head in all but the first pair and the last two pairs of ribs. However, cranial thoracic disc extrusions (T1–T9 region) do occur, most commonly in large-breed dogs, and most frequently affecting the German shepherd breed.[2,3] Type I disc extrusions usually occur between vertebral levels T11 and L3. The T12–T13 and T13–L1 discs are the most common sites for type I disc extrusions to occur in small-breed dogs. English cocker spaniels are more likely to experience midlumbar and caudal lumbar disc extrusions, in comparison with dachshunds.[4] There are a number of distinguishing clinical features of French bulldogs that experience thoracolumbar type I disc extrusions that differ from dachshunds. French bulldogs tend to experience lumbar disc extrusions more commonly than dachshunds, especially if there is a concurrent kyphotic/kyphoscoliotic thoracic vertebral malformation in the thoracic vertebral region. In one retrospective study comparing type I intervertebral disc extrusions between 47 French bulldogs and 671 dachshunds, 89% of the French bulldogs had an unrelated (to the disc extrusion) and clinically insignificant thoracic vertebral anomaly (vs. one dachshund). In this study, several significant clinical features were identified in French bulldogs versus dachshunds: younger age at clinical presentation (median of 3 years vs. 5 years), a higher male predominance, and more likelihood of developing progressive hemorrhagic myelomalacia in patients without DPP in the pelvic limbs.[5] In larger dogs, the L1–L2 and L2–L3 disc spaces are the most common sites for type I extrusions. The L4–L5 intervertebral disc space appears to be the most common site for thoracolumbar disc extrusion in cats.

DIAGNOSIS

Clinical Presentation

Signalment

The typical signalment for patients with thoracolumbar disc disease is essentially the same as that described in Chapter 40 (see p. 1376). Although most dogs that present with type I disc extrusions are small breeds, large-breed dogs are also occasionally afflicted by type I disc extrusions. Large dog breeds that seem to be most commonly encountered with type I disc extrusions include mixed breed, German shepherds, Labrador retrievers, Doberman pinschers, and Rottweilers.

History

Historical complaints associated with thoracolumbar disc extrusion are usually related to pain or varying degrees of pelvic limb weakness. The most common neurosurgical emergency encountered in small animal practice is acute onset of nonambulatory paraparesis or paraplegia due to the sudden extrusion of a thoracolumbar disc.

Physical Examination Findings

Although patients with signs of back pain with minimal to no neurologic deficits are occasionally encountered, type I thoracolumbar disc extrusions more typically result in acute paraparesis or paraplegia. This may be due to limited epidural space in the thoracolumbar vertebral canal compared with the cervical region. These patients often exhibit back pain in the general area of the disc extrusion. We occasionally encounter patients with type I disc extrusions in the caudal lumbar region that exhibit a pelvic limb root signature on the side of the extrusion; this phenomenon appears to be more common in spaniel breeds. Type II thoracolumbar disc protrusions typically cause progressive signs of paraparesis, often with some degree of back pain.

Diagnostic Imaging

Diagnostic imaging for suspected disc extrusion/protrusion is discussed in Chapter 40 under cervical disc disease (see p. 1376). In general, detailed spinal radiographs alone are often of limited value in a typical case of a type I disc extrusion.[6] Spinal radiographs may not reveal the site of active disc extrusion (i.e., there may be collapsed disc spaces of no clinical consequence in addition to the one causing clinical signs of disease), do not provide information regarding spinal cord swelling or hemorrhage, and often require sedation or general anesthesia for proper positioning and technique. Survey spinal radiographs are useful in ruling out vertebral neoplasia or discospondylitis but otherwise will not contribute to case management in the typical type I disc extrusion scenario (e.g., young adult dachshund with acute onset of myelopathy). In our opinion, anesthetizing a patient with a

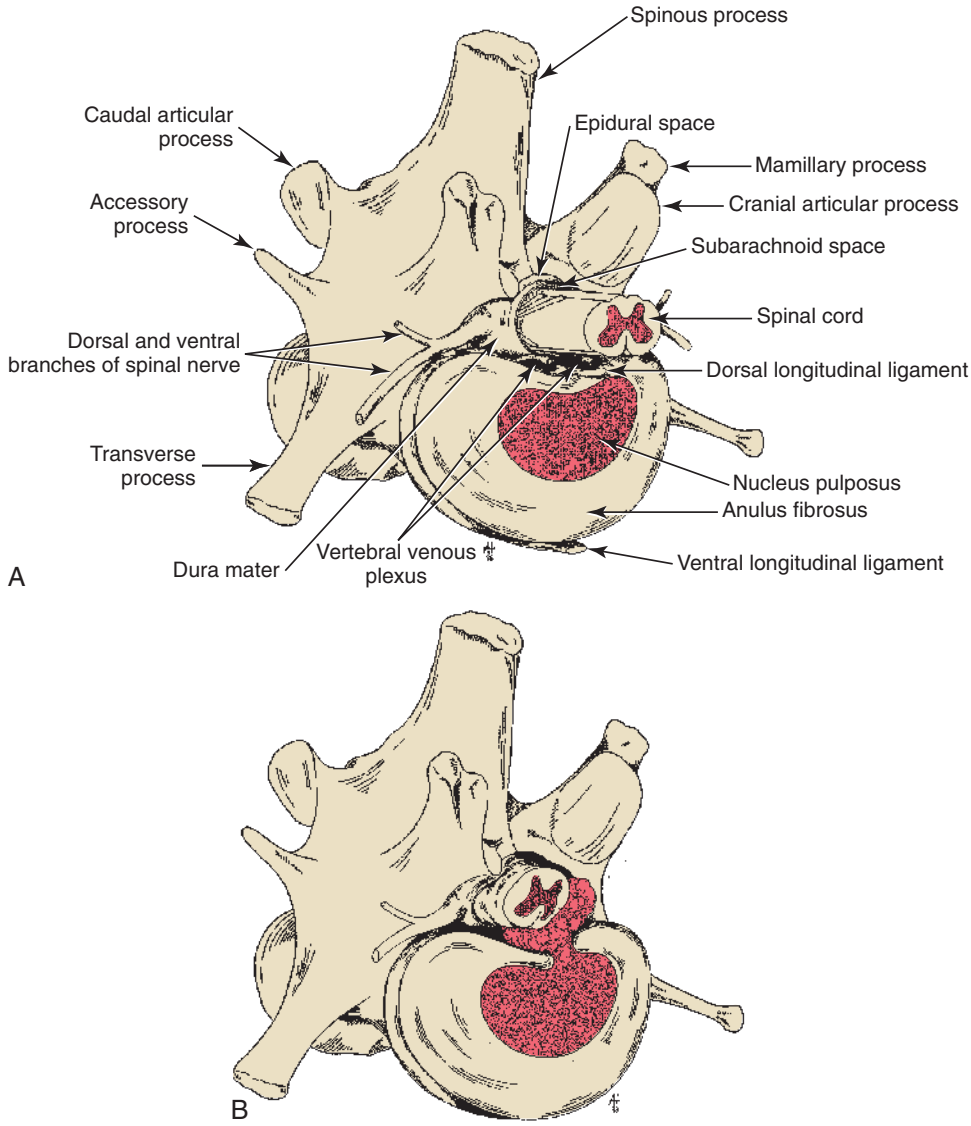

FIG. 41.17 Anatomic structures associated with a (A) normal and (B) extruded thoracolumbar disc.

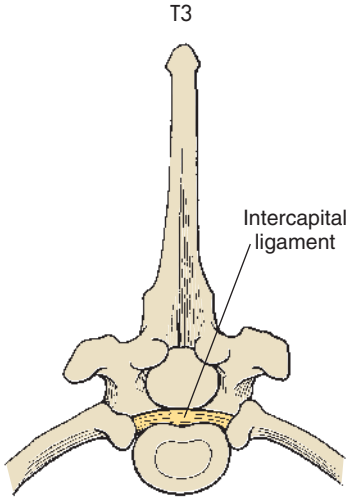

FIG. 41.18 Attachment of the intercapital ligament to each rib head. The ligament spans the dorsal annulus fibrosus.

suspected type I disc extrusion for imaging should not be undertaken unless surgical intervention is planned to follow the imaging, should a compressive lesion be identified. Myelography (Fig. 41.19) is still performed for diagnosing acute type I disc extrusions in dogs, but magnetic resonance imaging (MRI) is performed more frequently for this purpose (Fig. 41.20), and we consider it the imaging mode of choice. Computed tomography (CT) alone or with contrast (CT/myelogram) is another viable imaging modality for diagnosing type I disc extrusions (Fig. 41.21). In one prospective study of dogs with surgically confirmed intervertebral disc extrusions, MRI was found to be more sensitive (98.5%) than CT (88.6%) in correctly identifying the site of disc herniation and also more accurate than CT in discerning disc extrusions from disc protrusions.[7] Certain specific MRI characteristics have been shown to be useful in differentiating disc extrusions (type I) from disc protrusions (type II); protrusions tend to be on midline (extrusions are often lateralized), are typically confined to the disc space (extrusions are more dispersed), and are associated with partial disc degeneration

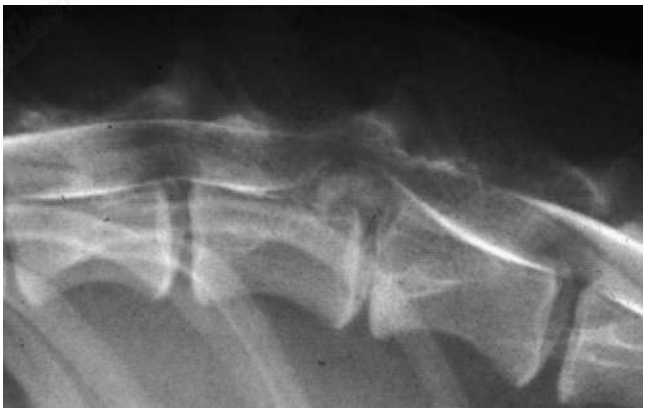

FIG. 41.19 Lateral myelogram showing a type I disc extrusion at T13–L1.

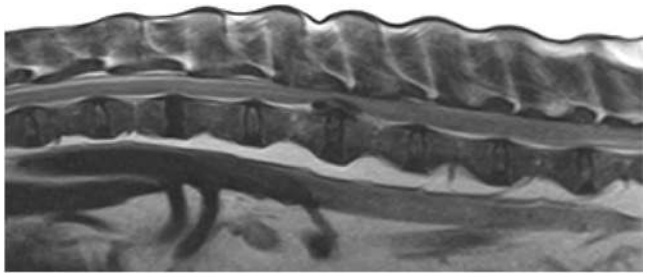

FIG. 41.20 Midsagittal T2-weighted magnetic resonance image showing an L2–L3 disc rupture.

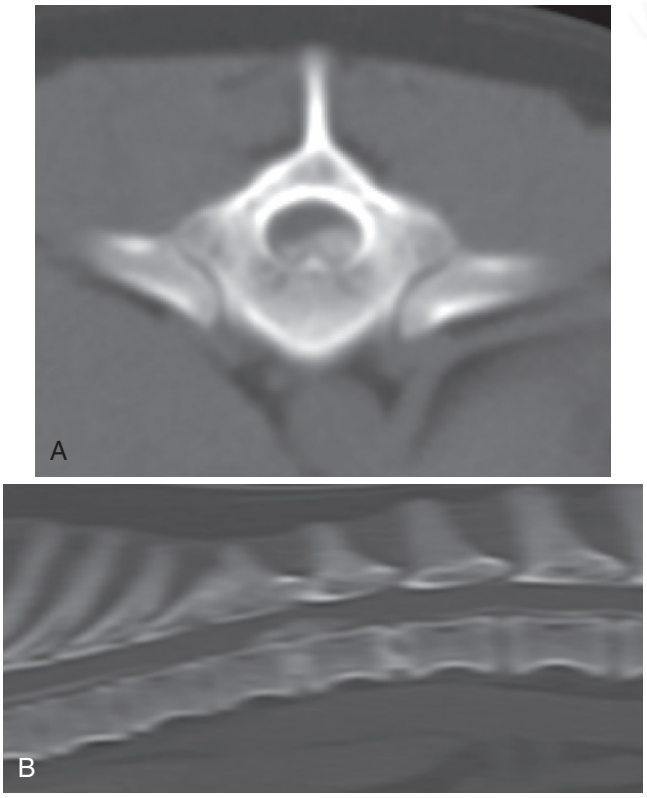

FIG. 41.21 (A) Axial and (B) sagittal reconstructed computed tomography images of a dog with a type I disc extrusion at T13–L1.

(extrusions are usually associated with a completely degenerated disc).[8,9] Several reports have described intramedullary disc extrusions. In this scenario, nuclear material extrudes with enough force to penetrate the meninges and enter the spinal cord. A characteristic MRI feature in such a case is a linear tract extending from the affected disc space into the spinal cord.

Laboratory Findings

Results of complete blood count and biochemistry profile analysis are typically normal. A stress leukogram may be observed on complete blood count results due to the underlying disease, prior administration of glucocorticoids, or a combination of these factors. Hepatic enzyme elevations (especially alkaline phosphatase) may be evident with dogs that have been treated with glucocorticoids. Urinary tract infection (UTI) may occur, especially in dogs treated previously with steroids. If the patient is still receiving glucocorticoids, it might not have pyuria or hematuria despite severe infection. Even if collected before a myelogram, cerebrospinal fluid (CSF) is often is evaluated if clear evidence of a disc compression is seen on imaging. Results of CSF analysis with type I disc extrusions are variable. Although CSF findings in type I disc extrusions have classically been characterized as normal to mildly inflammatory, moderate to marked pleocytosis with increased protein concentration is a common finding.

DIFFERENTIAL DIAGNOSIS

Multiple differential diagnoses are known for patients with suspected disc extrusions/protrusions, and their likelihood depends primarily on the signalment and history. Degenerative myelopathy is a potential differential for progressive type II disc protrusion in older dogs with progressive signs of T3–L3 myelopathy, especially in breeds at risk for this disorder (e.g., German shepherds, Pembroke Welsh corgis). Similarly, spinal neoplasia is a viable differential diagnosis in this situation. In some brachycephalic breeds, especially in young dogs, the presence of kyphotic/kyphoscoliotic vertebral malformations (e.g., hemivertebrae) is a possible cause for thoracolumbar myelopathy. As mentioned previously, such malformations are often incidental findings and may divert the clinician's attention away from the active lesion site (e.g., a disc extrusion elsewhere in the thoracolumbar spine). When such malformations are the cause of myelopathy, the anatomic abnormality is typically striking (an acute kyphotic angle [Cobb angle]) and there is evidence (MRI, myelography) of spinal cord compression; kyphotic/kyphotic vertebral abnormalities are discussed in more detail later in this chapter. Isolated thoracolumbar syrinx formation is not very common but can also cause a T3–L3 myelopathy; such cases are usually associated with local aberrations of laminar CSF flow Inflammatory disorders (e.g., discospondylitis, spinal granulomatous meningoencephalomyelitis, epidural empyema) may mimic signs of intervertebral disc extrusion. Ischemic/vascular events (e.g., fibrocartilaginous embolic myelopathy) can also mimic acute type I disc extrusion, especially in the early stages of that disorder. Most patients with vascular events to the spinal cord exhibit minimal to no evidence of spinal hyperpathia, in contrast to that exhibited by patients with type I disc extrusion.

MEDICAL MANAGEMENT

Medical management for patients with type I or type II disc disease is discussed in detail in Chapter 40 (under cervical disc disease,

pp. 1378–1379) and is identical to that for thoracolumbar disc disease. As in type I cervical disc extrusion patients, the validity of prolonged (e.g., 3–4 weeks) confinement has been questioned. In one large retrospective study,[10] the duration of crate confinement did not affect outcome, and the use of glucocorticoids had a negative effect on outcome. In this study, 54.7% of dogs were considered treatment successes, 30.9% initially responded to medical therapy then relapsed, and 14.4% were considered treatment failures. The mean and median duration of crate confinement in successfully and unsuccessfully managed dogs in this study was approximately 2 weeks. In another retrospective study concerning medical treatment of ambulatory dogs with suspected thoracolumbar disc extrusions (back pain with mild neurologic deficits), all 78 dogs had an initial positive response to medical treatment, but 50% of them (39 dogs) subsequently experienced recurrence of clinical signs (median follow-up time, 25 months).[11] Other reports of medically treated dogs with presumptive thoracolumbar disc extrusions presenting primarily for back pain cite recurrence rates of approximately 30% to 40% as well. Enforced rest is thought to minimize further disc extrusion into the vertebral canal, while allowing tears in the annulus fibrosus to heal (preventing further disc extrusion). The inflammatory reaction caused by the extruded disc material is thought to subside during this enforced resting period. If confinement therapy is successful, the patient should be allowed to return gradually to a normal level of activity over a period of 4 to 6 weeks. Owners need to be informed that the patient may acutely worsen during confinement and, especially with thoracolumbar disc disease, may become a surgical emergency.

SURGICAL TREATMENT

Indications for surgical intervention for patients with type I disc extrusions include recurrent or unrelenting back pain, worsening neurologic status despite the retention of ambulatory status, and nonambulatory paraparesis or paraplegia. In these scenarios, the time course of events is commonly acute and rapidly progressive. Indications for surgical intervention are similar for patients with type II disc protrusions, although such cases are usually much more chronic in nature.

Preoperative Management

Preoperative management of the patient undergoing thoracolumbar spinal surgery is discussed on p. 1404.

Anesthesia

See p. 1366 for anesthetic management of animals undergoing surgery of the spine. In addition, see Table 32.1 for anesthetic considerations in the stable orthopedic patient.

Surgical Anatomy

See p. 1404 for pertinent surgical anatomy of the thoracolumbar spine.

Positioning

Patient positioning for approaching the thoracolumbar spine is discussed on p. 1406.

SURGICAL TECHNIQUE

Hemilaminectomy is the most commonly performed surgical procedure for decompressing the spinal cord and removing extruded disc material and hemorrhage for type I disc extrusion patients. Dorsal laminectomy and combined hemilaminectomy/dorsal laminectomy procedures are also occasionally performed in these patients. Hemilaminectomy and dorsal laminectomy procedures are described on pp. 1406 to 1408. Removal of type I disc material and durotomy are described in Chapter 40 under cervical disc disease (see pp. 1375–1381). Fenestration is typically performed by retracting the spinal nerve and associated vessels cranially with a Freer elevator and incising the lateral annulus with a No. 11 blade (Fig. 41.22). Multiple methods and indications have been proposed for thoracolumbar disc fenestration. Most recent data support fenestration of degenerated discs within the confines of the surgical approach for a spinal decompression and disc removal as an *adjunctive preventative* procedure (i.e., to prevent further disc

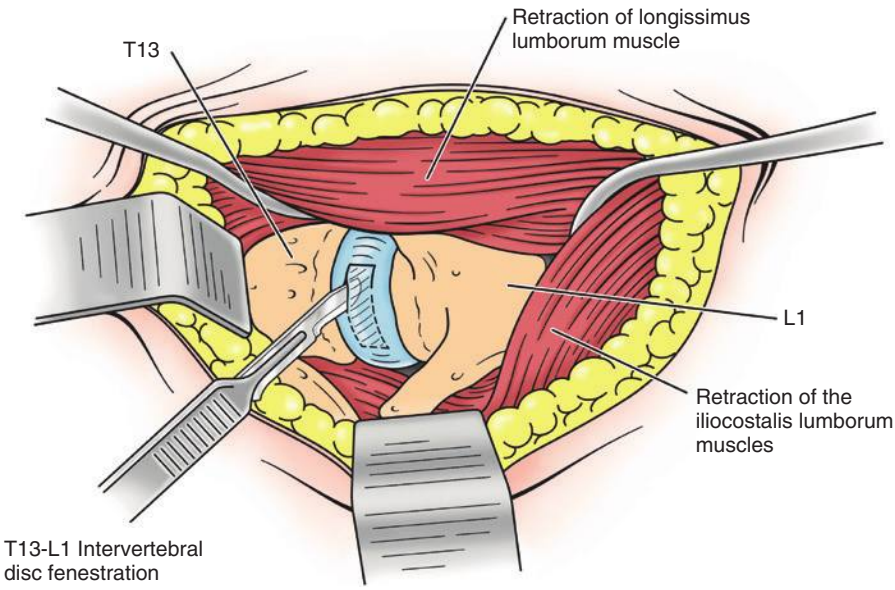

FIG. 41.22 Fenestration of a thoracolumbar disc with a No. 11 scalpel blade.

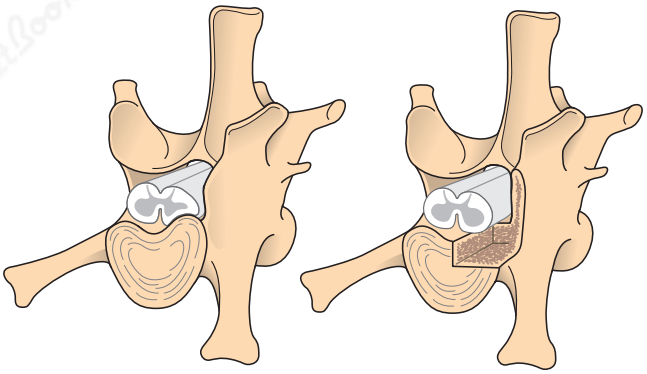

FIG. 41.23 Schematic illustration of the lateral corpectomy procedure (caudal vertebra shown).

extrusions). In one retrospective study of 662 dogs with thoracolumbar disc extrusions treated with hemilaminectomy with or without fenestration of adjacent disc spaces, a recurrent episode of disc extrusion was 26 times more likely to occur in fenestrated versus nonfenestrated discs.[12] Fenestration is never recommended as a sole procedure. Partial lateral corpectomy is a more recently described procedure, primarily for addressing chronic type II disc protrusions in dogs, in which a lateral slot is created ventral to the spinal cord and the protruded disc (Fig. 41.23). *Position the dog in lateral or ventral recumbency, and perform a dorsal, lateral, or dorsolateral approach to the spine (clinician preference), as previously described (pp. 1405–1408). Expose the lateral aspect of the annulus fibrosus and adjacent vertebral bodies, and retract the spinal nerve and associated blood vessels cranially with a probe (e.g., Gross ear hook and spoon). Fenestrate the disc of interest with a No. 11 scalpel blade. Use a high-speed air drill to create the lateral slot in the vertebral bodies and intervening disc.* The dimensions of the slot are somewhat dependent on presurgical imaging findings but are approximately as follows: one-fourth the caudal vertebral length for the caudal margin; one-fourth the cranial vertebral length for the cranial margin; one-half the vertebral body height for the ventral margin; and one-half to two-thirds the vertebral body width for the depth of the slot defect. *Drill through outer cortical and inner cancellous bone along the longitudinal axis of the spine, as well as through the intervening disc. Control hemorrhage from the cancellous bone with bone wax. Carefully drill to the level of the inner cortical bone dorsally until it is thin enough to flake off with a probe or remove with Lempert rongeurs. Remove this final layer of periosteum and remaining annulus material to expose the dorsal longitudinal ligament. Control venous sinus hemorrhage (if necessary) with Gelfoam and/or Surgicel. Close the incision routinely.*

SUTURE MATERIALS AND SPECIAL INSTRUMENTS

To perform a hemilaminectomy or a dorsal laminectomy, a high-speed air drill, Freer elevators and/or Army-Navy osteotomes (large dogs), Lempert rongeurs, Surgical, Gelfoam, bone wax, sterile cotton applicators, Gelpi retractors, Bishop-Harmon forceps, a Thompson ear hook and spoon (probe), and bipolar cautery are recommended.

POSTOPERATIVE CARE AND ASSESSMENT

Postoperative care and assessment for the patient undergoing surgery for thoracolumbar disc disease is similar to what has been described for other thoracolumbar disorders (see p. 1409). Intravenous analgesic drugs are administered as needed for the initial 24 to 48 hours after surgery, and oral analgesic drugs are continued, if needed. Patients are generally hospitalized for a minimum of 72 hours. In general, patients can be sent home before regaining ambulatory status, but we prefer to delay hospital discharge (if possible) until the patient is urinary continent (if continence was lost). Patients are generally rechecked 2 weeks after hospital discharge and every 1 to 2 months thereafter until fully recovered.

COMPLICATIONS

Potential complications of decompressive spinal surgery for disc extrusion/protrusion include neurologic worsening, hemorrhage, postoperative infection, and seroma formation. Postoperative UTIs are common in dogs with thoracolumbar disc extrusions. In many cases, UTIs are subclinical and may occur before surgery and up to several months following surgery. These findings emphasize the need to routinely monitor such patients for UTI and to treat them accordingly. Commonly incriminated organisms include *Escherichia coli, Enterococcus* species, and *Staphylococcus pseudintermedius*. Female dogs are more likely to develop UTI than males, and dogs not administered perioperative antibiotics are more likely to develop a UTI. Other factors that are significantly associated with an increased chance of UTI included nonambulatory status (especially with advancing age), inability to urinate voluntarily, and length of hypothermia while under anesthesia. In a 2016 retrospective study of 38 dogs that underwent hemilaminectomy for thoracolumbar disc extrusion, there was a 20.5% prevalence of UTIs over a 6-week evaluation period; in this study, no difference in likelihood of UTI development was found when dogs treated perioperatively with intravenous cefazolin were compared with those treated with subcutaneous cefovecin (Convenia).[13] The majority of UTIs experienced by postoperative thoracolumbar disc disease patients are not characterized by multiple drug-resistant organisms.

PROGNOSIS

Functional recovery for surgically treated patients with type I thoracolumbar disc extrusions and intact pain perception (nociception) to the pelvic limbs is expected in roughly 80% to 95% of cases (reports range from 72%–100%). In one large retrospective study involving 620 dogs with thoracolumbar disc extrusions and intact pelvic limb pain perception, 606 (97.7%) were ambulatory after surgery.[14] The majority of patients who are nonambulatory after surgery (with intact pelvic limb pain perception) will reach ambulatory status within 2 weeks postsurgery. No difference in outcome has been reported between dogs with UMN and lower motor neuron pelvic limb dysfunction with thoracolumbar disc extrusions. Neither the degree of spinal cord compression nor whether disc extrusions are focal or dispersed on MRI is associated with prognosis in surgically treated dogs with type I thoracolumbar disc extrusions. The prognosis appears to be similarly favorable for cats with intervertebral disc extrusions treated surgically.

Loss of clinically detectable DPP (see p. 1336) in the pelvic limbs occurs with some frequency in type I thoracolumbar disc disease and is associated with a guarded to poor prognosis. In this subset of patients, the length of time elapsed from loss of DPP to surgical decompression has been reported to be inversely associated with prognosis. Unfortunately, an accurate estimate of when DPP was

lost in a particular patient is often not attainable in clinical practice, and the time of onset of paraplegia is often substituted. Most reports suggest a functional recovery rate of approximately 50% (between 25% and 78%) for paraplegic dogs that have lost DPP to the pelvic limbs. In the large retrospective study mentioned earlier, 110 of 211 dogs (52%) with paraplegia and loss of pelvic limb DPP became ambulatory postsurgery.[14] There is a tendency (based on some of the older published literature) for better functional results to be expected when dogs with absent DPP are operated on within 12 hours of losing DPP. Conversely, there is a long-held belief that paraplegic dogs with loss of DPP for more than 48 hours are not viable surgical candidates; based on more recent clinical studies, this contention appears to be inaccurate. In one prospective study of 78 dogs with paraplegia and lack of DPP due to thoracolumbar disc extrusions, there was no significant association between the timing of surgery in relation to the onset of paraplegia and eventual outcome; in other words, the long-held dogma of a 48 hour "window" of expected successful surgical intervention for dogs with no DPP was disproven. In this study, 58% of dogs regained ambulatory status postsurgery.[15] It is our opinion that timely surgical intervention is warranted in such cases, as surgery may alleviate ongoing spinal cord compression; however, assigning a 48-hour cut-off point for such intervention is not justifiable. Similarly, as concussive parenchymal spinal cord (at the moment of impact) injury is not likely to be affected by surgical intervention, and the relative contribution of such injury (vs. compression) is typically unknown, the concept of a 12-hour "window of opportunity" is probably inaccurate. The development of focal or diffuse myelomalacia (liquefaction of the spinal cord parenchyma) is a concern with dogs that have lost pain perception and can usually be ruled in or out only at surgery (via a durotomy). Unfortunately, even with surgical confirmation of myelomalacia in dogs with no DPP, some level of subjectivity remains. Dogs with focal myelomalacia may still recover function, although the likelihood of this is unknown and performance of a durotomy may not have an effect on outcome. We routinely perform durotomies in dogs with no DPP to inspect the spinal cord for prognostic purposes. Dogs with no DPP before surgery that eventually recover ambulatory function tend to do so over longer time periods than dogs that had DPP before surgery. Although loss of DPP to the pelvic limbs is a negative prognostic indicator, the surgeon should be cautioned against being too "heavy-handed" in these situations.

The prognosis for functional recovery of dogs with chronic thoracolumbar disc protrusions treated via partial lateral corpectomy appears to be favorable in the majority of cases. In one retrospective study of 107 dogs with chronic intervertebral disc disease, 91.4% of dogs were ambulatory at final follow-up.[16] This procedure has also been demonstrated to be a viable option for acute disc extrusions.[17] Partial lateral corpectomy can also be performed in more than one site, for dogs with multiple disc lesions. In one retrospective study of 17 dogs, the use of multiple lateral corpectomies was found to be effective and without clinical evidence of vertebral instability.[18]

HEMIVERTEBRA (KYPHOTIC/KYPHOSCOLIOTIC VERTEBRAL MALFORMATIONS)

DEFINITIONS

Hemivertebra is a term widely (and often inappropriately) used to describe a number of vertebral body abnormalities that lead to kyphosis and scoliosis of the vertebral column. Another commonly used term for these malformations is "butterfly vertebra," although this term refers specifically to vertebrae with a butterfly shape when viewed dorsoventrally. These vertebral anomalies are usually characterized by lack of complete formation of the vertebral body. A more comprehensive radiographic classification system for thoracic vertebral anomalies in dogs has recently been proposed and is based on schemes similar to those used in humans (Fig. 41.24).[19] According to this scheme, kyphosis is more likely to develop with ventral hypoplasia (ventral wedge shape), ventral aplasia, and ventrolateral aplasia of the vertebral body. Although these malformations can be incidental findings in many cases, the resultant wedge-shaped vertebra or vertebrae sometimes cause an unstable segment with spinal cord compression.

GENERAL CONSIDERATIONS AND CLINICALLY RELEVANT PATHOPHYSIOLOGY

In cases of kyphotic/kyphoscoliotic vertebral malformations, part of the vertebra fails to form properly, usually the vertebral body. The abnormal vertebra usually has a wedge or cuneiform shape. Malformations of the vertebral bodies in the thoracic spinal region of dogs are generally believed to be due to failure of vertebral ossification centers to form, fuse properly, or both during embryonic or fetal development. The etiology of this abnormal development is not fully understood, but factors such as genetic defects, teratogenic insults and abnormal intersegmental blood supply to the developing vertebral column have been implicated. In humans with vertebral body malformations, genetic mutations have been identified in genes responsible for regulating normal fetal vertebral segmentation. In both humans and dogs, the vertebral malformations that tend to cause neurologic deficits are primarily those that lead to kyphosis (dorsal curvature) of the vertebral column. The midthoracic region of the vertebral common is most commonly affected, usually between T6 and T9. The malformed vertebra or vertebrae lead to varying degrees of abnormal angulation of the spine, most commonly kyphosis and scoliosis. In addition to compression of the spinal cord at the level of the malformation, instability may play a role in the development of myelopathy in clinically affected dogs.[20]

DIAGNOSIS

Clinical Presentation

Signalment

Thoracic vertebral body anomalies leading to kyphosis most commonly occur in small-breed dogs, particularly the brachycephalic screw-tailed breeds (English bulldog, French bulldog, pug, Boston terrier). The abnormal shape of the tail in these breeds is thought to be due to similar malformations in the coccygeal vertebral bodies. These thoracic vertebral anomalies are occasionally encountered in other small-breed (e.g., Yorkshire terrier, West Highland white terrier, dachshund, Pekingese, Chihuahua, Maltese) and large-breed (e.g., Doberman pinscher, German shorthaired pointer) dogs. This is thought to be a heritable trait in the screw-tailed breeds, and the disorder in German shorthaired pointer dogs is believed to be autosomal recessive. There is a wide age range at the time of clinical presentation, with approximately 60% being less than 1 year old and 40% greater than 1 year old. There does not appear to be any obvious sex predilection for this disorder.

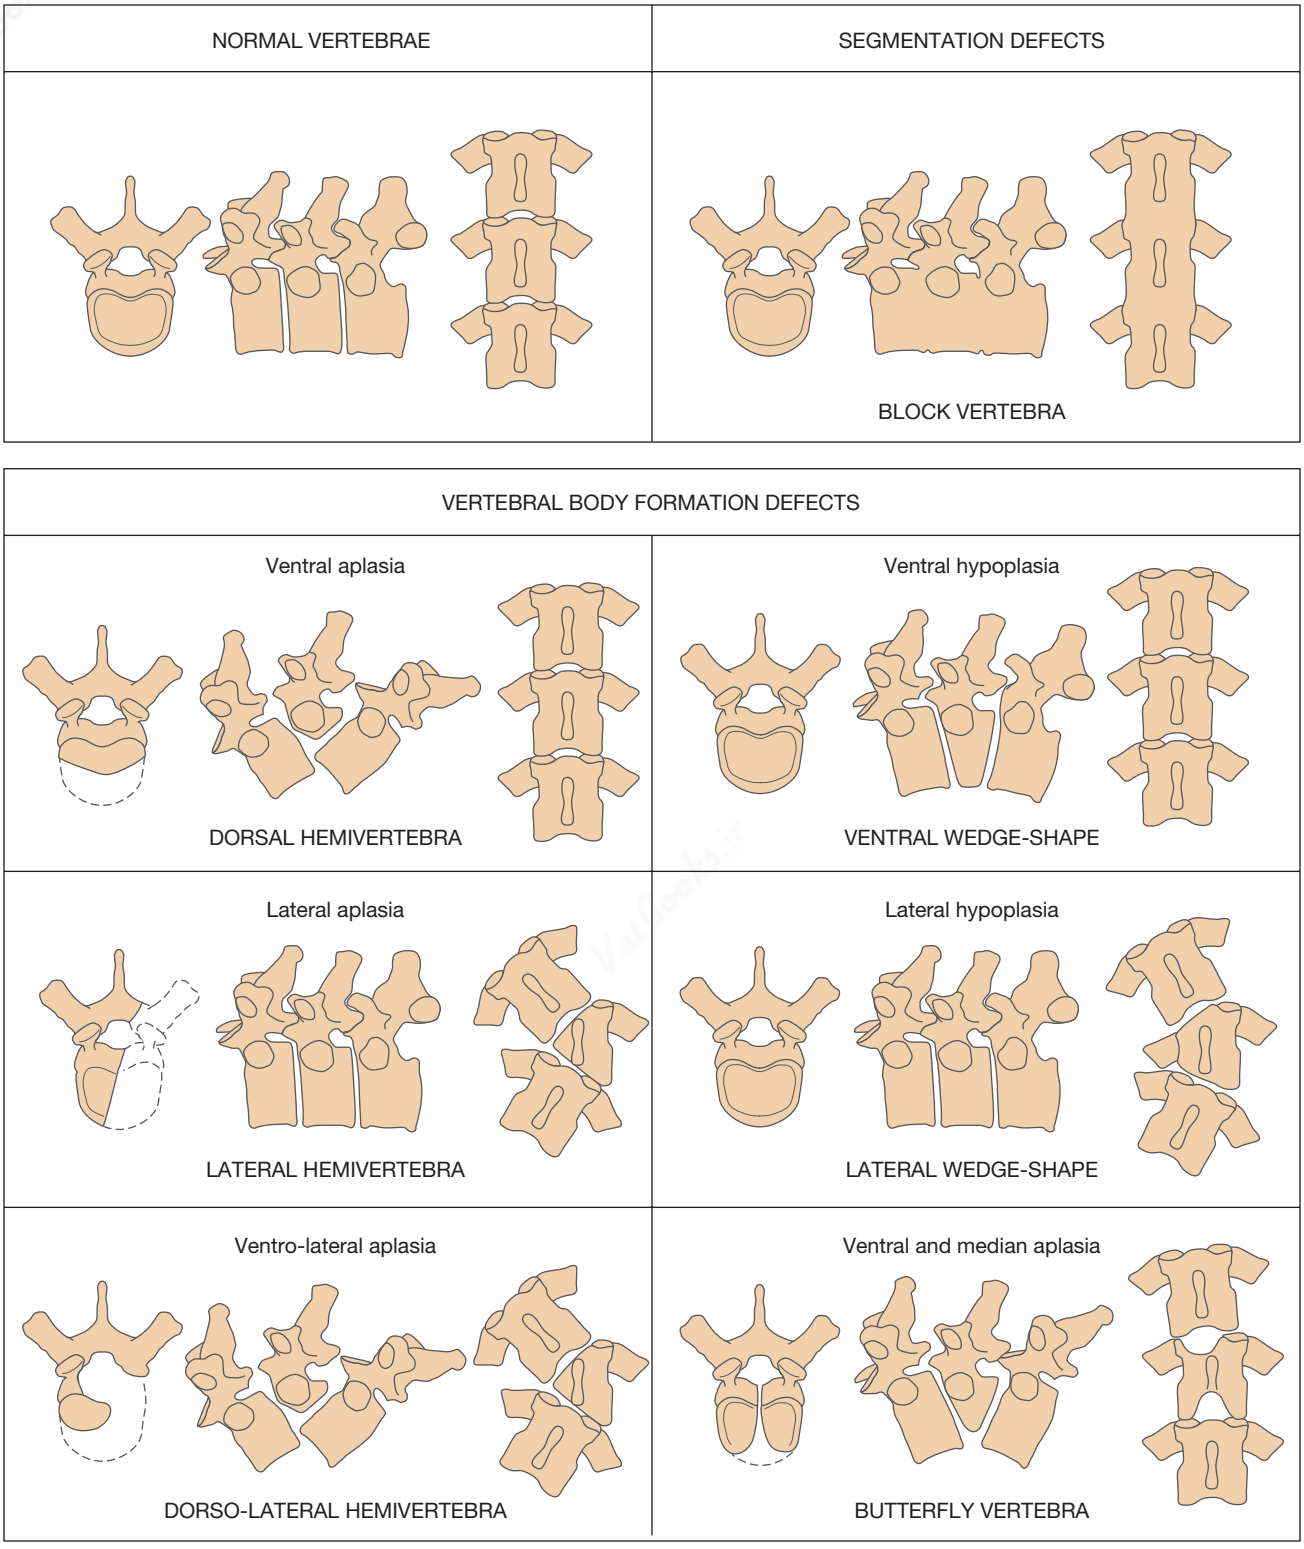

FIG. 41.24 Proposed radiographic classification system for thoracic vertebral anomalies in dogs based on schemes similar to those used in humans. (Modified from Gutierrez-Quintana R, Guevar J, Stalin C, et al. A proposed radiographic classification scheme for thoracic vertebral malformations in brachycephalic "screw-tailed" dog breeds. *Vet Radiol Ultrasound.* 2014;55[6]:585–591.)

History

The typical history for a dog with a kyphotic vertebral body malformation is a progressive T3–L3 myelopathy. The rate of progression and the severity of dysfunction are variable with this disorder. Some dogs may become nonambulatory over a period of days, and others may progress over weeks to months. We have operated on several affected dogs who had suffered an acute type I disc extrusion in the vicinity of the abnormal vertebral segments. In one small retrospective study (14 dogs), it was found that dogs with kyphoscoliotic thoracic vertebral malformations tended to have degenerative discs adjacent to the malformed vertebral segment.[21]

Physical Examination Findings

Affected dogs typically exhibit clinical signs consistent with a T3–L3 myelopathy. Neurologic severity can vary from back pain with mild ataxia to paralysis and loss of DPP to the pelvic limbs.

Diagnostic Imaging

Imaging options for the diagnosis of kyphoscoliotic vertebral malformations include radiography, myelography, CT, and MRI. Survey radiographs are typically obtained initially, identifying the kyphotic segment. In dogs considered surgical candidates, we prefer to perform MRI first, followed by CT imaging of the area of vertebral malformation. MRI gives superior soft tissue detail (Fig. 41.25), as well as axial images. CT alone or combined with myelographic contrast agent provides excellent bony detail, especially when three-dimensional reconstruction images are created. We have found preoperative CT images to be most useful for surgical planning in these cases. In the vast majority of dogs, the malformed vertebra or vertebrae responsible for the deviation of the vertebral column will be located in the mid to caudal thoracic vertebral region, usually between T6 and T9. In one report,[19] the most commonly affected vertebra was T7, followed by T8 and T12. Scoliosis is typically not associated with neurologic dysfunction. The degree of kyphosis has been associated with the presence of neurologic dysfunction in both dogs and humans. The degree of angulation of the vertebral segment associated with the anomalous vertebra or vertebrae can be quantified by measuring the Cobb angle (Fig. 41.26). The Cobb angle is derived from the intersection of two lines: one at the cranial aspect of the kyphotic vertebral segment and the other at the caudal aspect of the segment. In one retrospective study, a significant difference in kyphotic Cobb angles was appreciated between dogs with and without neurologic dysfunction; the majority of dogs with neurologic dysfunction had a Cobb angle associated with the kyphotic vertebral segment greater than 35 degrees.[22]

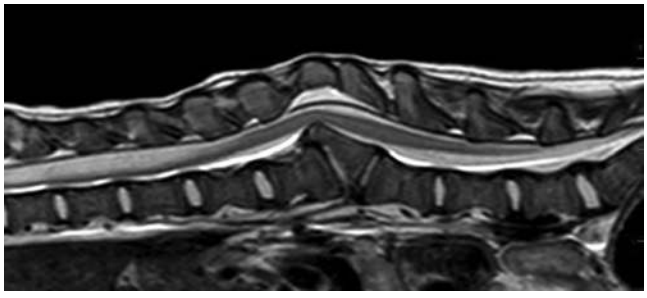

FIG. 41.25 Sagittal T2-weighted magnetic resonance spinal image of a dog with a hemivertebra and spinal cord compression.

Laboratory Findings

Laboratory findings are typically normal. Some mild laboratory abnormalities may be associated with prior glucocorticoid administration.

DIFFERENTIAL DIAGNOSIS

In young patients, differential diagnoses include intervertebral disc extrusion, inflammatory/infectious disease, and trauma. It is extremely important to differentiate dogs with acute type I disc extrusions and incidental thoracic vertebral anomalies from dogs whose vertebral anomalies are the cause of the myelopathy. Neoplasia is also a differential diagnosis but is more likely with older patients.

MEDICAL MANAGEMENT

Medical management of dogs with hemivertebra is similar to that described for patients with intervertebral disc disease (p. 1378), but more prolonged confinement or limited activity is recommended because of suspected instability.

SURGICAL TREATMENT

Preoperative Management

Preoperative management of the patient undergoing thoracolumbar spinal surgery is discussed on p. 1404.

Anesthesia

See p. 1366 for anesthetic management of animals undergoing surgery of the spine. In addition, see Table 32.1 for anesthetic considerations in the stable orthopedic patient.

Surgical Anatomy

See p. 1404 for pertinent surgical anatomy of the thoracolumbar spine.

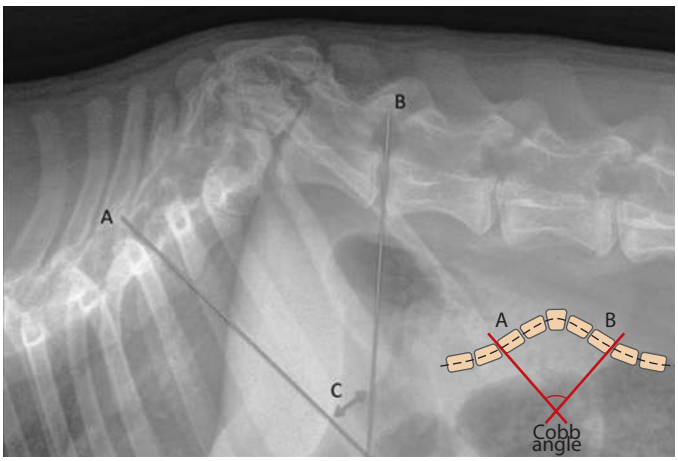

FIG. 41.26 Lateral thoracic radiograph from a dog with a vertebral malformation. The intersection of two lines (*A*) cranial and (*B*) caudal to the malformation show the Cobb angle of 47 degrees (*C*). (From Dewey CW, Davies E, Bouma JL. Kyphosis and kyphoscoliosis associated with congenital malformations of the thoracic vertebral bodies in dogs. *Vet Clin North Am Small Anim Pract.* 2016;46[2]:295–306.)

Positioning

Patient positioning for approaching the thoracolumbar spine is discussed on pp. 1405 to 1408.

SURGICAL TECHNIQUE

The two most commonly employed methods to stabilize kyphoscoliotic vertebral segments are modified segmental spinal fixation (spinal stapling) and vertebral body pins with polymethylmethacrylate (PMMA). These patients generally have unstable vertebral segments, and decompression without stabilization is contraindicated.

For modified segmental spinal fixation or pin/PMMA fixation, a dorsal approach to the cranial to midthoracic spine is performed with bilateral exposure of the dorsal spinous processes, laminae, and rib tubercles (see p. 1405). At least two, and preferably three, thoracic segments cranial and caudal to the region of suspected instability are included in the fixation. *For modified segmental spinal fixation, drill holes through the bases of the dorsal spinous processes to be included in the fixation, using a 0.045-inch or 0.062-inch (1.143 or 1.575 mm) Kirschner wire (K-wire) (the holes must accommodate the passing of 18- to 20-gauge orthopedic wire). Stay above the dorsal lamina when drilling the holes to prevent entrance into the vertebral canal. Pass lengths of orthopedic wire through the holes and lay them flat. Allow enough length of orthopedic wire on either side of the dorsal spinous processes to comfortably twist them around the "staples" to be placed alongside these processes. Choose two intramedullary (IM) pins of appropriate thickness for the patient (this needs to be "eyeballed" for each patient) to make the "staples." Using a handheld plate bender or a wire twister, bend the ends of the IM pins so that they can be placed around the cranial and caudal dorsal spinous processes at the limits of the fixation.* We prefer to place two staples facing opposite directions (Fig. 41.27), with one staple located inside the other (e.g., one staple spanning two vertebrae cranial and caudal to the site of instability, the other spanning three vertebrae). *Place these IM pins on top of the previously placed orthopedic wires, to lie against the dorsal lamina. Tighten the orthopedic wires around the IM pins using a wire twister. In the cranial and midthoracic region, orthopedic wires looped around the rib heads can be incorporated into the fixation. In the caudal thoracic and lumbar region, orthopedic wire passed through the articular processes (predrilled holes) can also be used. To perform pin/PMMA fixation, select the appropriately sized positive profile threaded pins to place in the vertebral bodies.* Because of limited room for error in pin placement in this region and the abnormal anatomy present in these patients, presurgical measurement for implant placement based on axial MRI or CT images is recommended. *In the cranial and midthoracic spinal region, insert pins into the transverse process, slightly less than halfway from the rib articulation (tubercle of the rib articulating with the transverse process of the vertebra) medially to the upward slope of the lamina as it meets the dorsal spinous process laterally. This is also at the level of or just medial to the mammillary process (a dorsally projecting knoblike eminence on the transverse process). Angle the pins fairly acutely, approximately 20 to 30 degrees from vertical (Fig. 41.28). The proper angle of insertion into the vertebral body is very close to the joint angle between the rib tubercle and the transverse process. Placing a small K-wire into this joint space may help in achieving the correct trajectory for implant placement (Fig. 41.29). Insert the pins to engage the far cortex of the vertebral body, but the tips of the pins should not extend more than a few millimeters past the bone. Insert these pins bilaterally. Place PMMA over the pins bilaterally, with or without an IM pin within the PMMA for reinforcement (Fig. 41.30).*

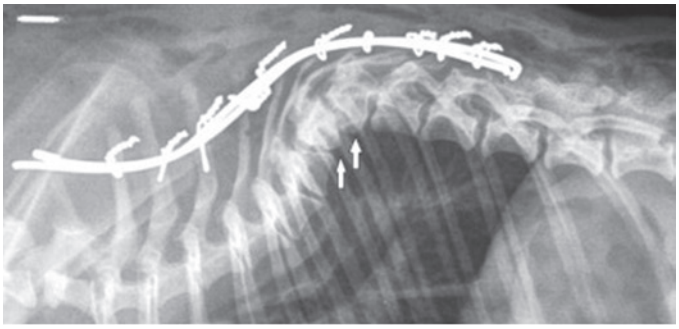

FIG. 41.27 Lateral radiograph showing postoperative segmental spinal implants to stabilize the vertebral column in a young dog with a thoracic vertebral malformation. Image shows the use of wire to stabilize the segments. (From Charalambous M, Jeffery ND, Smith PM, et al. Surgical treatment of dorsal hemivertebrae associated with kyphosis by spinal segmentation stabilization, with or without decompression. *Vet J.* 2014;202[2]: 267–273.)

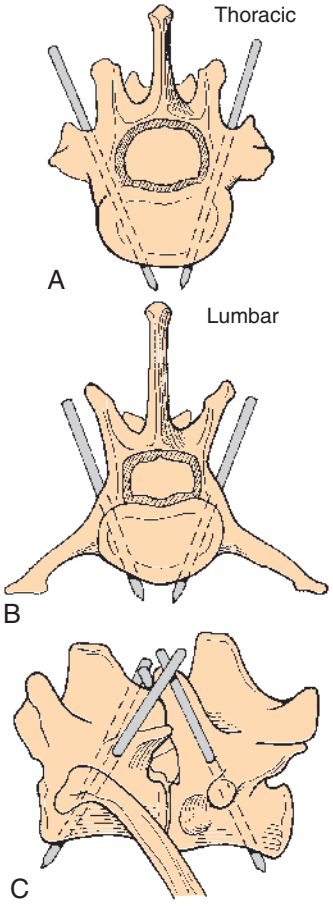

FIG. 41.28 Approximate angles of insertion of pins for (A) thoracic and (B) lumbar vertebrae. (C) Lateral view at thoracolumbar junction.

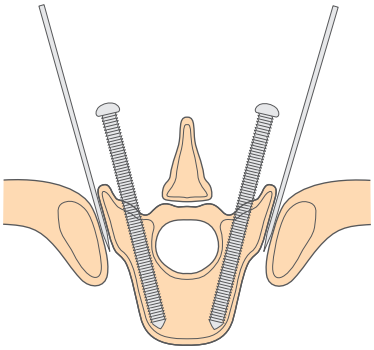

FIG. 41.29 Illustration depicting the placement of a vertebral body pin in a cranial-midthoracic vertebra. A small K-wire has been placed in the joint between the rib tubercle and transverse process to estimate the proper angle of insertion.

The PMMA should be doughy and should not stick to the surgeon's fingers when it is ready to be placed. *Close the incision routinely.*

We prefer a surgical technique that is a hybrid of the two techniques described earlier (Fig. 41.31). A hemilaminectomy is performed over the kyphotic segment. Vertebral body pins are placed in the side of the hemilaminectomy, and a spinal staple is placed on the opposite side. In this method, the trajectory of the spinal cord can be visualized while placing vertebral body pins. Regardless of the surgical method of vertebral stabilization chosen, either postoperative radiographs or CT imaging is recommended to assess the adequacy of implant placement.

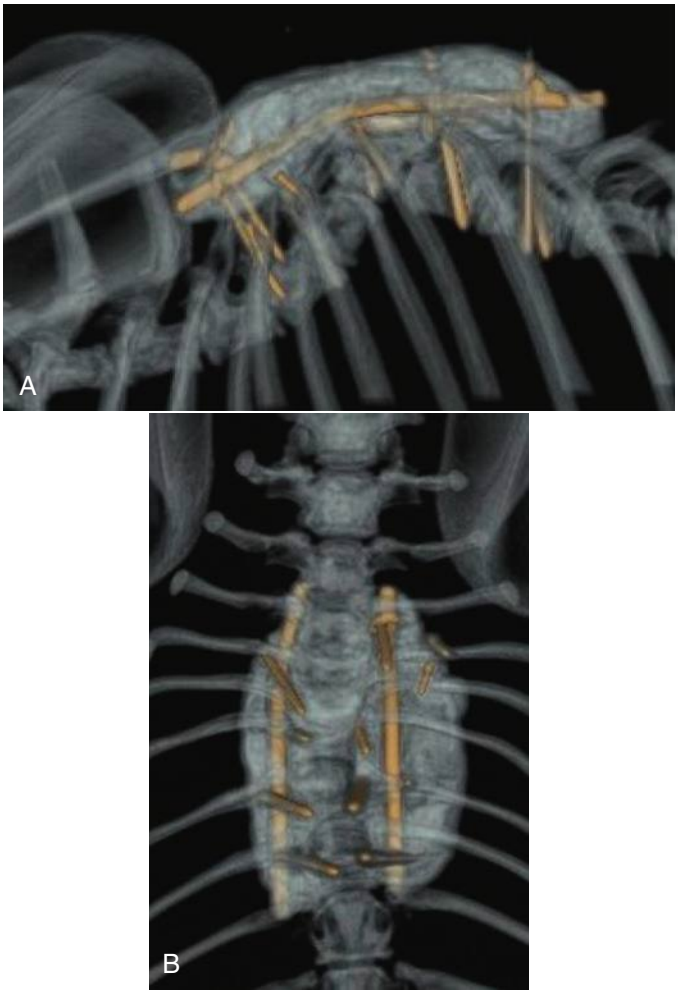

FIG. 41.30 (A) Lateral and (B) ventral views of three-dimensional reconstructed computed tomography images showing postoperative vertebral body pin and polymethylmethacrylate stabilization following dorsal laminectomy to decompress the spinal cord in a young dog with a thoracic vertebral malformation.

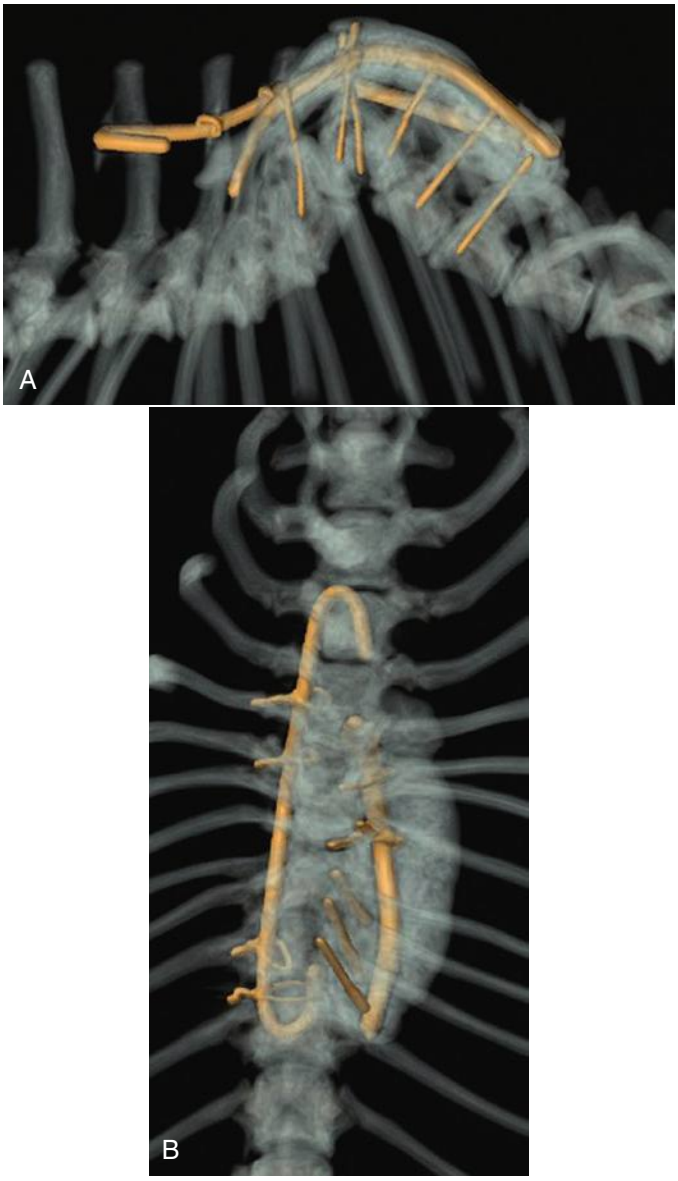

FIG. 41.31 (A) Lateral and (B) ventral views of three-dimensional reconstructed computed tomography images showing postoperative hybrid stabilization using two of the most common techniques following hemilaminectomy to decompress the spinal cord in a young dog with a thoracic vertebral malformation.

SUTURE MATERIALS AND SPECIAL INSTRUMENTS

Basic instruments needed to perform thoracolumbar spinal surgery are covered on pp. 1374 and 1414. In addition to these instruments, a mini-driver, IM pins, cerclage wire, and PMMA will be required.

POSTOPERATIVE CARE AND ASSESSMENT

Postoperative care and assessment is similar to that described for thoracolumbar disc disease (see p. 1409). Longer periods of analgesic drugs are often required owing to implant placement, and longer periods of confinement/limited activity are imposed to prevent premature loosening or breaking of implants.

COMPLICATIONS

Complications associated with thoracolumbar spinal surgery are discussed on p. 1410. Potential complications of pin/PMMA fixation include inadvertent penetration of the vertebral canal and iatrogenic spinal cord damage. In addition to these complications, implant failure and infection are potential complications of this surgery. Pneumothorax may occur during surgery, especially if wires are placed around the rib heads.

PROGNOSIS

Limited reports have described the surgical management of dogs with kyphoscoliotic vertebral anomalies experiencing clinical signs of myelopathy. However, stabilization of the abnormal vertebral segment, with or without decompression, has been successful in most reported cases.[20]

SPINAL NEOPLASIA

DEFINITIONS

Spinal neoplasia refers to primary and secondary tumors of the vertebrae and/or spinal cord parenchyma. **Primary tumors** include those neoplasms that arise from spinal cord parenchyma (e.g., neurons, glial cells) or associated meningeal/ependymal tissue. **Secondary tumors** include tumors that arise from structures extrinsic to the spinal cord and its meningeal covering. Such tumors include primary or metastatic vertebral neoplasms, malignant nerve sheath tumors, and metastases to the extradural space or the cord parenchyma (intramedullary metastases).

GENERAL CONSIDERATIONS AND CLINICALLY RELEVANT PATHOPHYSIOLOGY

Spinal neoplasia is discussed in detail in Chapter 40 (see pp. 1396–1399).

DIAGNOSIS

Clinical Presentation

Signalment

General signalment aspects for spinal neoplasia are discussed in Chapter 40 (p. 1397). Spinal nephroblastoma is a thoracolumbar neoplasm (occurs between 10th thoracic and third lumbar vertebral levels) of dogs that is typically diagnosed between 6 months and 3 years of age. German shepherds and retrievers appear to be predisposed to developing nephroblastoma.

History

As with cervical spinal neoplasms, thoracolumbar spinal cord tumors most often have slowly progressive signs of myelopathy (e.g., back pain, paraparesis). However, some neoplasms may have more rapid onset and progression of neurologic dysfunction (e.g., lymphoma in cats).

Physical Examination Findings

Focal back pain and varying degrees of pelvic limb ataxia and weakness are characteristic physical examination findings in dogs with thoracolumbar spinal neoplasia.

Diagnostic Imaging

Diagnostic imaging for suspected thoracolumbar neoplasia is identical to that described for cervical spinal neoplasia (see p. 1397). Nephroblastoma is typically in an intradural extramedullary location (Fig. 41.32).

Laboratory Findings

As with cervical spinal neoplasia, specific laboratory abnormalities are unlikely with thoracolumbar spinal neoplasia (see p. 1398).

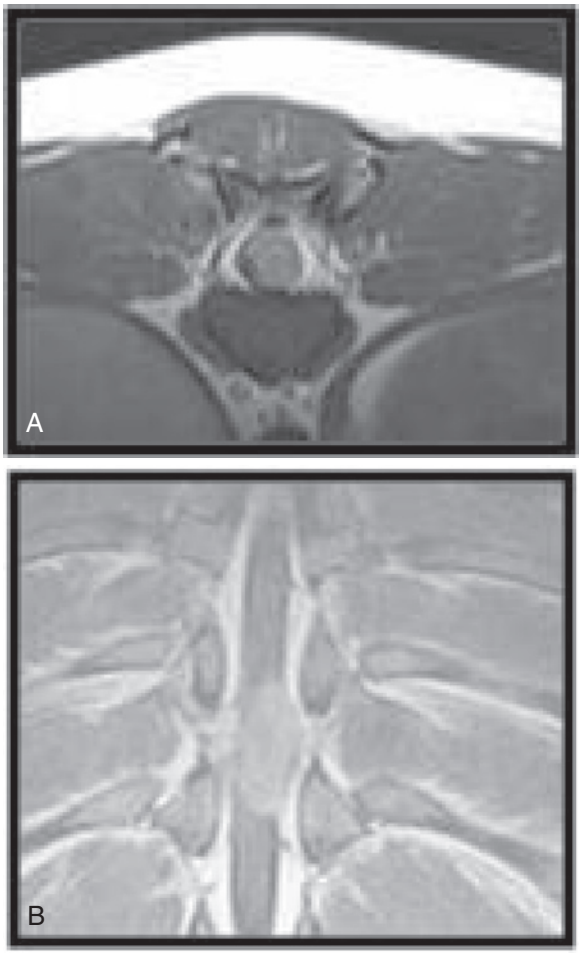

FIG. 41.32 (A) Axial and (B) dorsal T1-weighted with contrast images of a spinal nephroblastoma in a dog.

DIFFERENTIAL DIAGNOSIS

The main differential diagnoses for thoracolumbar neoplasia are disc protrusion/extrusion and inflammatory/infectious disease (e.g., discospondylitis; see p. 1456). Tentative diagnosis of specific tumor type is based on specific tumor location on imaging studies in combination with signalment information (e.g., extradural mass in a young cat is most likely lymphoma).

MEDICAL MANAGEMENT

Medical management of spinal neoplasia is discussed in Chapter 40 (see p. 1398).

SURGICAL TREATMENT

Preoperative Management

Preoperative management of the patient undergoing thoracolumbar spinal surgery is discussed on p. 1404.

Anesthesia

See p. 1366 for anesthetic management of animals undergoing surgery of the spine. In addition, see Table 32.1 for anesthetic considerations in the stable orthopedic patient.

Surgical Anatomy

See p. 1404 for pertinent surgical anatomy of the thoracolumbar spine.

Positioning

Patient positioning for approaching the thoracolumbar spine is discussed on pp. 1405 to 1408.

SURGICAL TECHNIQUE

Hemilaminectomy, dorsal laminectomy, or a combination of the two procedures is used to access spinal cord and nerve root tumors. These approaches are described on pp. 1405 to 1408. Spinal stabilization may be necessary if vertebral masses are debulked or removed. Goals of surgery are to decompress the spinal cord and remove neoplastic tissue for both reduction of cancer load and diagnosis.

SUTURE MATERIALS AND SPECIAL INSTRUMENTS

Basic instruments needed to perform thoracolumbar spinal surgery are covered on pp. 1374 and 1414. Additional instrumentation often required for effective tumor removal is discussed under cervical spinal neoplasia (see p. 1398).

POSTOPERATIVE CARE AND ASSESSMENT

Postoperative care and assessment is similar to that described for thoracolumbar disc disease (see p. 1409).

COMPLICATIONS

Similar to other thoracolumbar surgeries, potential complications include neurologic worsening postsurgery, intraoperative hemorrhage, and postoperative seroma formation. Other specific complications include inability to remove tumor tissue and implant-associated complications if implants are used (e.g., vertebral body tumor debulking with stabilization).

PROGNOSIS

Prognosis for different types of spinal neoplasia is discussed in Chapter 40 under cervical spinal neoplasia (see p. 1398). The prognosis for dogs with nephroblastoma undergoing surgical removal of the neoplasm has historically been thought of as favorable; however, the long-term prognosis after surgical resection may not be as positive as was previously believed. The median survival for dogs treated with surgery was reported as 70.5 days based on five dogs in one study, and 380 days in another study based on six dogs.[23,24] Whereas there is considerable variability in the survival times of dogs in these two studies, the assumption that most dogs with this neoplasm are effectively cured with surgical removal is clearly not valid and postoperative radiation therapy should be pursued in these dogs to help improve survival times.

SPINAL TRAUMA

DEFINITIONS

Spinal trauma is defined in Chapter 40 (see p. 1399).

GENERAL CONSIDERATIONS AND CLINICALLY RELEVANT PATHOPHYSIOLOGY

The pathophysiology of spinal trauma is discussed in Chapter 40. The thoracolumbar spine is the most common site for fracture/luxation in dogs and cats, and the most common cause is automobile trauma. Fracture/luxation of the caudal thoracic and caudal lumbar spinal regions is most frequently encountered, presumably because these regions are more mobile compared with vertebral segments cranial and caudal to them. It is very common for dogs and cats with thoracolumbar trauma to have associated injuries to other parts of the body (e.g., pneumothorax, pulmonary contusions, other orthopedic injuries), and a second region of spinal fracture/luxation is present in approximately 20% of these patients.

DIAGNOSIS

Clinical Presentation

Signalment

As with cervical spinal trauma (see p. 1400), no breed or sex predilection has been noted for thoracolumbar spinal trauma, but this type of injury tends to occur more commonly in younger animals (less than 5 years old).

History

As with cervical spinal trauma (see p. 1400), there is often a known history of automobile trauma in patients with thoracolumbar spinal injury. In some cases, the patient may have gone missing for some period of time before being discovered with evidence of back pain and paraparesis/paraplegia. Dogs and cats that have experienced external trauma may present for reasons other than thoracolumbar spinal trauma (e.g., pelvic fractures, appendicular fractures, brain injury). Neurologic deficits in these patients referable to a T3–L3 myelopathy may be subtle or overshadowed by the presenting problem. It is important to maintain a high index of suspicion for thoracolumbar spinal injury in such cases.

Physical Examination Findings

In addition to following the basic principles of shock management, the two most important aspects to consider when managing the dog or cat with suspected thoracolumbar spinal injury are (1) evaluate the patient for concurrent injuries (e.g., pneumothorax, pulmonary contusions, other orthopedic injuries) and (2) limit movement of the patient in case instability is present. If instability is suspected or confirmed, the patient should be immobilized (i.e., secured to a rigid structure), especially if that patient is to be transported elsewhere for care following emergency management of shock. If instability is suspected or confirmed, the neurologic examination is modified to prevent excessive motion of unstable vertebral segments. The spine is carefully palpated for areas of abnormal contour and hyperesthesia. When the toes of the pelvic limb are checked for the presence or absence of DPP, it is important that the spine does not move when the dog or cat withdraws the limb; this movement may cause motion of the fracture/luxation site and subsequent pain, which may be falsely interpreted as pain sensation coming from the toes being stimulated by the examiner.

Diagnostic Imaging

Diagnostic imaging for spinal fracture/luxation is discussed in Chapter 40 for cervical spinal injury (p. 1400). The amount of vertebral displacement apparent on imaging is not necessarily indicative of the extent of parenchymal damage. After fracture/luxation occurs, segments can move back into some degree of realignment, even if displacement at the time of injury was complete, causing spinal cord transection. We prefer complete spinal radiographs initially and CT images preoperatively and postoperatively if surgery is to be performed.

Laboratory Findings

As with dogs and cats with cervical spinal injuries (p. 1400), patients with isolated thoracolumbar spinal injuries often have unremarkable laboratory findings (e.g., stress leukogram, elevated hepatic enzyme levels). Injury to other organ systems may result in other laboratory abnormalities (e.g., abnormal arterial blood gas values with pulmonary injury, elevated blood urea nitrogen and creatinine with damage to the urinary tract).

DIFFERENTIAL DIAGNOSIS

As with cervical spinal injury (see p. 1400), there are no reasonable differential diagnoses if the traumatic event was witnessed. Concurrent traumatic disc extrusion is not common but should be considered. Thoracolumbar fracture/luxation following minor trauma should prompt a search for an underlying pathology (e.g., tumor, infection, hyperparathyroidism). As mentioned, other associated traumatic injuries need to be identified and addressed in dogs and cats with known thoracolumbar spine trauma.

MEDICAL MANAGEMENT

General medical management for spinal trauma is discussed in Chapter 40 (see p. 1401). Medical management for dogs and cats with thoracolumbar fracture/luxation is typically chosen for cases with minimal evidence of displacement and suspected low level of instability (e.g., compression fractures). In some cases, this therapeutic route is chosen primarily for financial reasons. Medical management for thoracolumbar fracture/luxation generally includes strict confinement, a back brace, and drugs for pain management. Several options for constructing a back brace are available. The brace should be well padded (e.g., cast padding) and should incorporate a stiff material (e.g., fiberglass, metal rods). The surgeon should assume that the brace affords a small amount of additional stabilization to the patient; strict confinement is still paramount even with a well-constructed brace. Some patients may need to be sedated during the confinement period, depending on their demeanor. Multiple options are available for parenteral and oral analgesic therapy in dogs and cats (see Chapter 13).

Thoracolumbar spinal trauma patients treated via medical therapy alone may have protracted periods of recumbency and inactivity. It is extremely important to provide adequate padding (to avoid pressure sores), appropriate bladder care, frequent turning (to avoid pressure sores, atelectasis, and subsequent pneumonia), range-of-motion physiotherapy (to prevent muscle contracture), and proper nutrition and hydration. Use of a paraparetic cart is contraindicated in these patients; the cart may create a lever arm at the site of instability.

SURGICAL TREATMENT

Preoperative Management

Preoperative management of the patient undergoing thoracolumbar spinal surgery is discussed on p. 1404.

Anesthesia

See p. 1366 for anesthetic management of animals undergoing surgery of the spine. In addition, see Table 32.2 for anesthetic considerations in the orthopedic trauma patient.

Surgical Anatomy

See p. 1404 for pertinent surgical anatomy of the thoracolumbar spine.

Positioning

Patient positioning for approaching the thoracolumbar spine is discussed on pp. 1405 to 1408.

SURGICAL TECHNIQUE

Depending on the specific site, approach the spine bilaterally as described on pp. 1405 to 1408 (dorsal approach to the cranial and midthoracic spine, dorsal approach to the thoracolumbar spine). If a hemilaminectomy, a dorsal laminectomy, or a combined procedure is indicated, perform the desired procedure as described on pp. 1406 to 1408. During exposure, avoid excessive motion of the unstable segment, using bipolar cautery and sharp dissection if necessary. Place penetrating towel clamps or bone-holding forceps (e.g., speed-lock reduction forceps) on the dorsal spinous processes cranial and caudal to the fracture/luxation, and use these to gently reduce the fracture/luxation. Visualize the adjacent articular process articulations (i.e., in the nondisplaced regions) to help judge the appropriate level of reduction (in the caudal thoracic and lumbar spine, the cranial process or facet generally sits more dorsally than the caudal articular process). From medial to lateral, place a small K-wire (0.035 or 0.045 inch [0.889 or 1.143 mm]) through the articular processes at the luxation site if possible (caudal process engaged first, then cranial process) once reduction is achieved (Fig. 41.33); this should maintain reduction while implants are

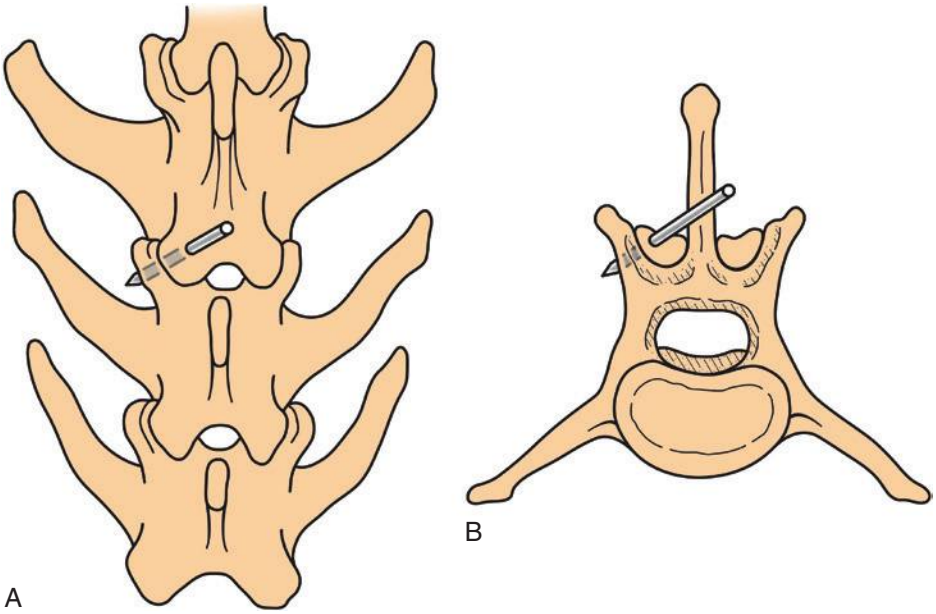

FIG. 41.33 Technique for temporary stabilization using a K-wire across the articular processes. (A) Dorsal view. (B) Axial view.

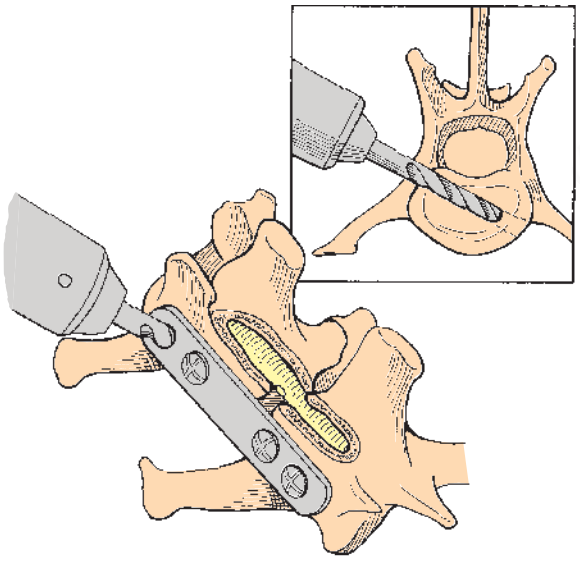

FIG. 41.34 Angle for screw placement in the lumbar vertebrae *(inset).*

being placed. Pin placement in the thoracic vertebrae and the technique for modified segmental spinal fixation are described under hemivertebra treatment (see p. 1418). Pin placement in the lumbar vertebrae is similar, but a less acute angle is taken; typically, 45 or more degrees from vertical (an angle of approximately 50–70 degrees) is used to predrill for plate screws (Fig. 41.34). The target area for vertebral implants in the lumbar region is between the base of the accessory process dorsally and the "elbow" of the transverse process ventrally. Screws (usually cortical) can be used in lieu of pins, depending on surgeon preference. When screws are used, they can be self-tapped after a guide hole is drilled, but we prefer to tap the holes first. Pin/PMMA or screw/PMMA fixation for thoracolumbar vertebral fracture/luxation is generally performed bilaterally (Fig. 41.35). Vertebral body plates can be placed in caudal thoracic vertebrae and lumbar vertebrae. In the thoracic region, the rib heads may need to be drilled down or disarticulated to accommodate the plate (Fig. 41.36). *When using plates in the lumbar region, drill a ventral plate "groove" parallel to the long axis of the spine at the base of the transverse process (Fig. 41.37) to help conform the plate to the vertebra and to prevent slipping during plate application. Engage a minimum of four cortices with screws on either side of a fracture/luxation when plates are used.*

Rhizotomy of the nerve roots is not always required when vertebral body plates are applied but may be necessary in some cases. Because of the risk of damaging nerve root contributions to the femoral nerve caudal to the L4 vertebra, some surgeons do not apply plates caudal to this vertebra. Plating beyond the L4 vertebral level also becomes technically difficult owing to interference by the ilial wings. Plating of the dorsal spinous processes using plastic or metal plates is a less commonly pursued option for thoracolumbar spine fracture/luxation (Fig. 41.38); incorporation of three vertebral segments cranial and caudal to the site of instability is recommended with this mode of stabilization. Closure is routine for all these methods of stabilization. Resection of epaxial musculature to effect closure usually is not required.

SUTURE MATERIALS AND SPECIAL INSTRUMENTS

In addition to standard instrumentation required for thoracolumbar spinal surgery (see p. 1414), positive-profile threaded pins, cortical and cancellous screws, bone plates and plating equipment, PMMA, and ASIF small fragment reduction forceps should be available. Depending on surgeon preference, specific dorsal spinous process plating systems (e.g., plastic spinal plates, steel Auburn plates) may also be desired.

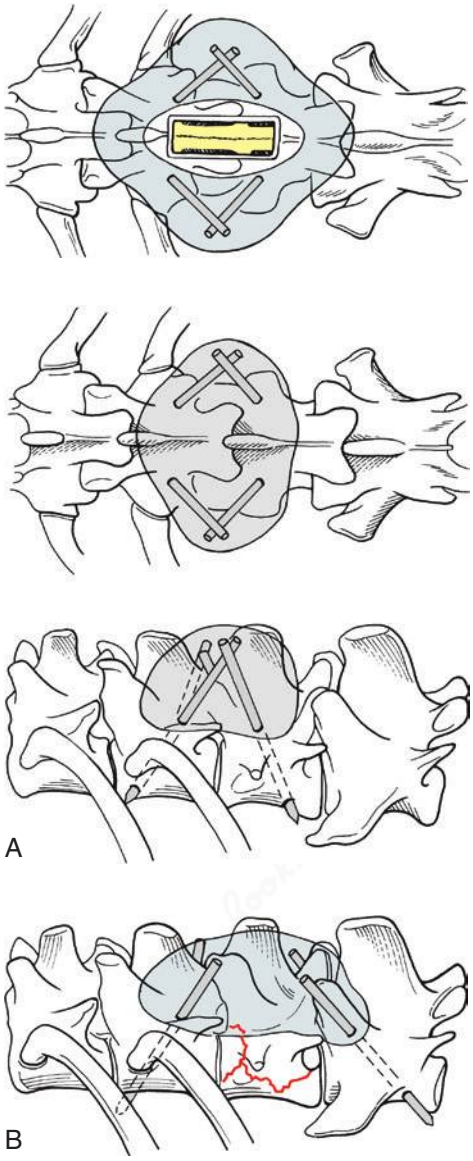

FIG. 41.35 Bilateral fixation with pins and polymethylmethacrylate (A) with and (B) without concurrent performance of a laminectomy.

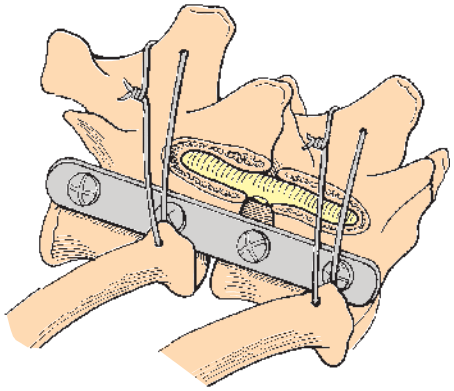

FIG. 41.36 Disarticulation of the rib heads to facilitate vertebral body placement in the caudal thoracic spine. The ribs have been wired to the dorsal spinous processes.

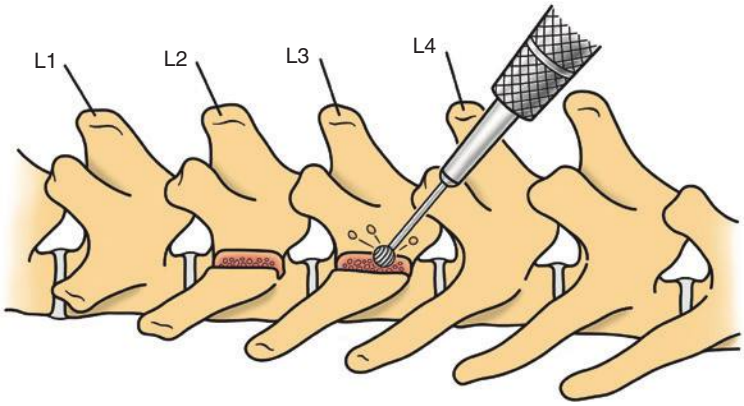

FIG. 41.37 Ventral plate groove created in the base of the transverse process of a lumbar vertebra.

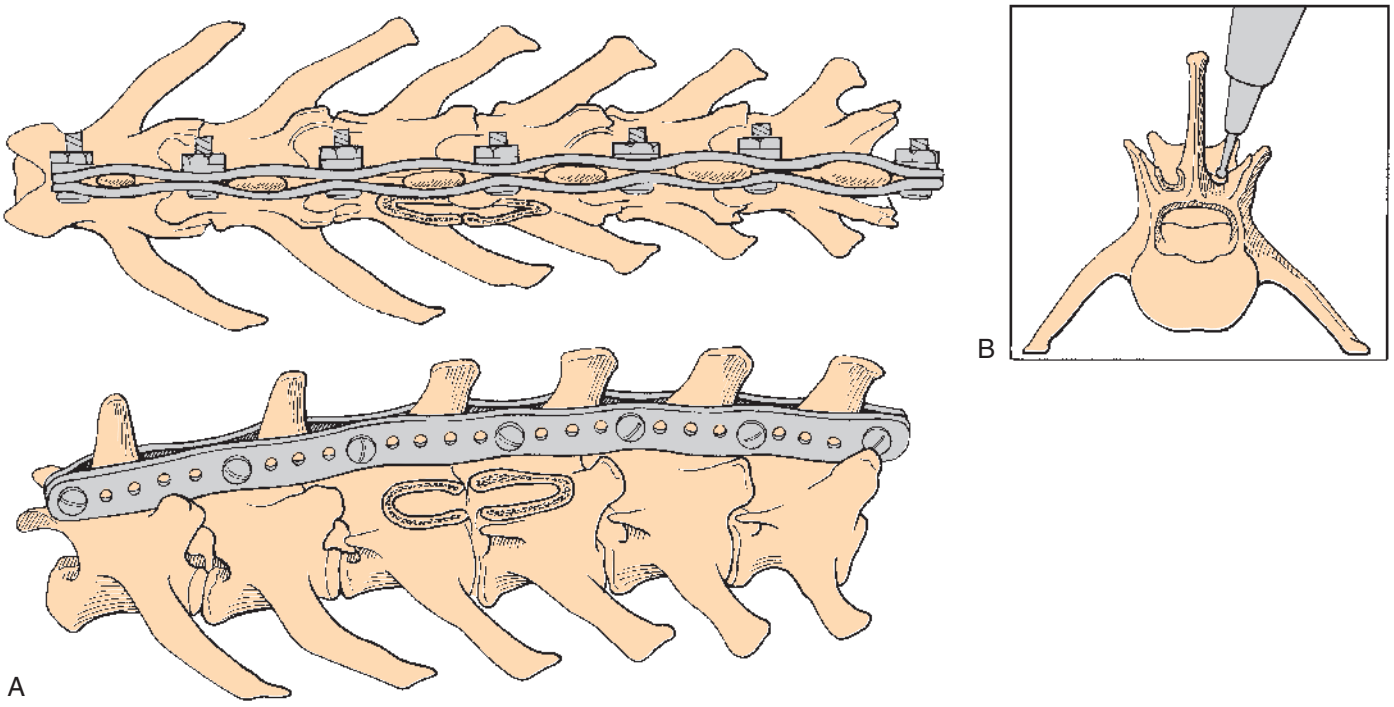

FIG. 41.38 (A) Place plastic dorsal spinous process plates on each side of the dorsal spinous processes. Place nuts and bolts through the plates and between spinous processes. (B) To facilitate uniform plate contact of all dorsal spinous processes spanned by the plate, remove any points of laminar or articular facet contact by the plates with a high-speed pneumatic drill.

POSTOPERATIVE CARE AND ASSESSMENT

Postoperative care and assessment of the thoracolumbar spinal trauma patient is similar to that described for the cervical spinal trauma patient (see p. 1402).

COMPLICATIONS

Complications of surgery for thoracolumbar spinal cord injury include neurologic worsening after surgery, improper implant placement (e.g., iatrogenic damage to the spinal cord, poor bone purchase), implant failure, implant migration, iatrogenic pneumothorax (with cranial and midthoracic vertebral fixation), postoperative infection, and postoperative seroma formation.

PROGNOSIS

In dogs and cats with preservation of DPP to the pelvic limbs, the prognosis for medical or surgical management is generally favorable. Unlike the situation with thoracolumbar intervertebral disc extrusion, loss of deep pain sensation with external trauma (e.g., automobile trauma) is associated with a very poor prognosis; estimates for functional recovery in such patients are generally less than 10%.

Surgery of the Cauda Equina

GENERAL PRINCIPLES AND TECHNIQUES

DEFINITIONS

The **cauda equina** is the leash of nerve roots derived from the terminal spinal cord segments from L7 caudally (Cd1–Cd5) that travel through the vertebral canal in the lumbosacral area. The **lumbosacral area**, or **lumbosacral junction**, is the bone (e.g., L7 vertebra, sacrum) and connective tissue (e.g., L7–S1 articular facet joint capsules, interarcuate ligament, disc) enclosing the cauda equina. **Dorsal laminectomy** is removal of the lamina; this usually entails partial or complete removal of the dorsal spinous process of L7 and cranial parts of the sacral spine. **Facetectomy** is partial or full removal of the L7–S1 articular processes (facets), and **foraminotomy** is the removal of specific regions of these processes to enlarge the L7–S1 intervertebral foramen. Both facetectomy and foraminotomy are used in this region of the spine to relieve pressure on the L7 nerve root if necessary. **Dysesthesia** and **paresthesia** are similar terms that describe abnormal sensations caused by irritation of nerve roots and/or nerves. Descriptions of such abnormal sensations in people include pricking, burning, and tingling. It is believed that dogs with cauda equina lesions have similar sensations because affected patients often stare or bite at areas around the rump and pelvic limbs.

GENERAL CONSIDERATIONS

The most common clinical sign associated with lesions of the cauda equina is pain (hyperesthesia). Hyperesthesia may arise from compression and/or inflammation of meninges and nerve roots of the cauda equina (particularly the L7 nerve roots), bony components of the lumbosacral area, L7–S1 disc, or L7–S1 articular process (facet) joint capsules. Hyperesthesia may be manifested in a number of ways. Some patients exhibit obvious discomfort when rising or sitting down. Others may be reluctant to jump or climb stairs. A unilateral or bilateral pelvic limb lameness, which may be exacerbated by increased activity, may also indicate hyperesthesia in the area of the lumbosacral region and cauda equina. With some conditions, the patient may appear to be in constant pain (e.g., discospondylitis, vertebral tumor), whereas in others, careful palpation of the lumbosacral area is required to elicit a painful response. Dogs and cats with cauda equina lesions often appear painful on extension of the coxofemoral joints. This may be because the extension is pulling on nerve roots that are already irritated by a disease process at the lumbosacral junction. Alternatively, these patients may have concurrent hip dysplasia that is not of clinical significance, or of lesser clinical significance than the cauda equina disorder. Because clinical signs of cauda equina disease can mimic those of hip dysplasia, it is important not to confuse the two disorders, especially in dogs that are predisposed to both disorders and may have radiologic evidence of hip dysplasia (e.g., German shepherds). There is evidence that the presence of lumbosacral transitional vertebrae is a predisposing factor for developing both degenerative lumbosacral stenosis (DLSS) and hip dysplasia.[1,2]

Proprioceptive deficits are also often evident in patients with cauda equina lesions. Interference with afferent proprioceptive fibers at the level of the cauda equina can produce various degrees of proprioceptive deficits to the pelvic limbs. This can be as mild as delayed proprioceptive positioning reactions or as severe as pelvic limb ataxia with dragging of the dorsal aspect of the toes (knuckling). Dogs with cauda equina lesions are not typically ataxic in the manner that ataxia is usually described; these dogs do not display truncal ataxia when walking; rather, they misstep occasionally and stumble. Proprioceptive deficits may or may not be symmetric. Voluntary motor deficits to the muscles innervated by the sciatic nerve and caudal (coccygeal-tail innervation) nerves may be clinically detectable, as the cord segments and nerve roots of the cauda equina give rise to these nerves. Pelvic limb weakness may be apparent with damage to sciatic nerve contributions, and decreased to absent tail tone and movement may occur with damage to caudal segments and/or nerve roots. During the stance phase of the pelvic limb gait, patients with cauda equina lesions will sometimes either internally or externally rotate the hind paw. This phenomenon may be due to lack of proprioception, but may also be due to interference with innervation to muscles responsible for hip rotation.

In some cases, the patient may exhibit an abnormally low tail carriage, which the owner often notices. Abnormal reflex activity such as decreased to absent withdrawal and gastrocnemius reflexes may be seen. In our experience, most dogs with progressive cauda equina compression (e.g., DLSS) have poor pelvic withdrawal reflexes only at the level of the hock. The patellar reflex is typically normal or may appear hyperreflexive. Caudal thigh muscles normally inhibit the action of the quadriceps muscle group when the patellar reflex is elicited. Removal of this tonic antagonistic influence by disrupting the nerve supply to the caudal thigh muscles may result in an apparently hyperactive patellar reflex (i.e., patellar pseudohyperreflexia). A decreased to absent perineal reflex may result from cauda equina lesions. Urinary and fecal abnormalities, with varying degrees of urinary and fecal incontinence, may occur with damage to sacral segments and/or roots. Bladder dysfunction is classically lower motor neuron (LMN) in

ABSTRACT

The lumbosacral region is most commonly afflicted by a disorder referred to as degenerative lumbosacral stenosis, which mainly affects middle-aged to older dogs. Standard surgical procedures for the lumbosacral spine include laminectomy, foraminotomy, facetectomy, and methods for surgical stabilization. A minimally invasive procedure for degenerative lumbosacral stenosis is described.

nature. Nociceptive (pain perception) deficits in areas of the pelvic limbs, perineum, and tail may occur with severe lesions of the cauda equina; these are usually traumatic in nature.

Preoperative Management

Specifics of preoperative management depend largely on the disease process. In cases of DLSS, most patients will benefit from analgesic drugs prior to scheduling for surgery. There are multiple options for oral analgesic drug therapy for these patients, including nonsteroidal antiinflammatory drugs (NSAIDs), tramadol, and either gabapentin or pregabalin (see Table 34.3). Pregabalin appears to be effective in relieving pain associated with nerve root compression in dogs with DLSS. In our opinion, there is no advantage of glucocorticoids over NSAIDs in patients with cauda equina lesions, and there are potential disadvantages of glucocorticoid use.

Patients with radiographic evidence of discospondylitis (see p. 1457) should be treated with appropriate antibiotic regimens (e.g., oral cefadroxil, 22 mg/kg every 8 hours or clindamycin, 11 mg/kg every 8 hours). The L7–S1 disc space is the most common site for discospondylitis, and some dogs will have this infectious process in addition to DLSS. It is prudent to control the infection before considering surgical decompression; in some cases, treatment of the infection resolves clinical signs of disease and surgery is not needed. In traumatic fractures/luxations of the lumbosacral area, treatment is similar to that described for trauma to other regions of the spine (see pp. 1399 and 1421). These patients need to be stabilized from a cardiovascular standpoint and evaluated for injury to other organ systems. Additionally, these patients need to be kept as immobile as possible to avoid further damage to the nerve roots of the cauda equina.

Anesthetic Considerations

Anesthetic management of the patient with a cauda equina lesion is similar to that described for patients with other spinal surgical disorders (see p. 1366).

Antibiotics

Intravenous (IV) antibiotics (e.g., cefazolin, 22 mg/kg IV) should be administered perioperatively (30 minutes before the initiation of surgery and every 90 to 120 minutes thereafter during surgery) and either discontinued after surgery or within 24 hours. In cases of suspected bacterial discospondylitis, oral antibiotics are administered long-term (months).

Surgical Anatomy

The lumbosacral junction has many features in common with other regions of the lumbar spine (see p. 1404), but there are several unique features (Fig. 42.1). The dorsal spinous process of L7 is considerably shorter than that of L6, and the intervertebral foramen of the lumbosacral junction is dorsoventrally flattened in comparison with cranial lumbar vertebrae. The lateral aspects of this foramen have been referred to as the *lateral recesses* and contain the L7 nerve root as it runs caudally toward the L7–S1 intervertebral foramen. The sacrum is composed of three fused vertebrae, and the fused dorsal spinous processes form a median sacral crest. The dorsal lamina of the sacrum is considerably thinner than the L7 dorsal lamina, and in small dogs and cats it may not have a visually distinguishable inner medullary cancellous bone layer. The prominent ilial wings of the pelvis project dorsally over the dorsal aspect of the sacrum and cranially to the level of the L6–L7 disc space.

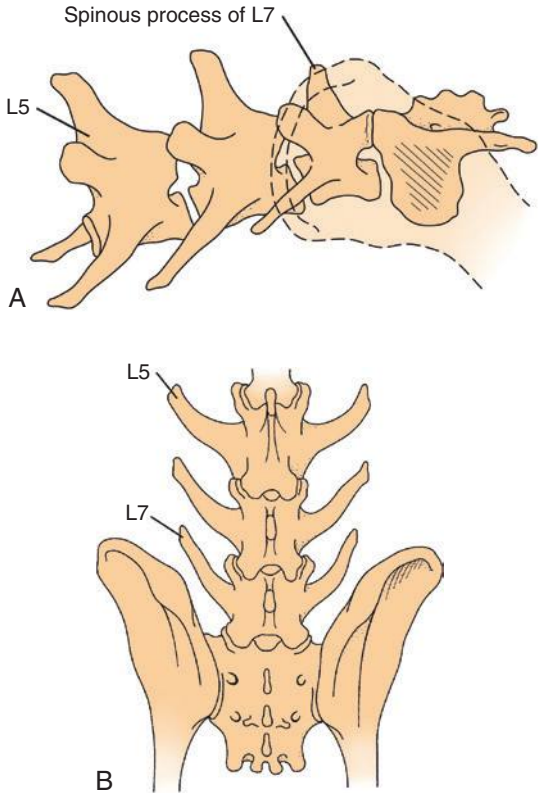

FIG. 42.1 Anatomy of the lumbosacral junction. (A) Lateral view. (B) Dorsal view.

Clinically relevant soft tissue structures in the lumbosacral junction include the termination of the spinal cord and the cauda equina nerve roots, as well as supportive joint and ligamentous tissues and blood vessels. In medium- to large-breed dogs, the spinal cord ends *(conus medullaris)* at the L6 or L7 vertebral level (Fig. 42.2). In small dogs and cats, the spinal cord terminates more caudally, around the S1 vertebral level. The *filum terminale* is a meningeal extension beyond the conus medullaris that attaches to the caudal (coccygeal) vertebrae. As in the rest of the vertebral canal, paired venous sinuses (internal vertebral venous plexuses) are located on the floor of the canal. *Radicular vessels* (artery and vein) travel through the L7–S1 intervertebral foramina along with the L7 nerve root. Small blood vessels also exit the dorsal sacral foramina; these are usually cauterized at surgery or occluded with bone wax. Supportive connective tissues at the lumbosacral junction include the intervertebral disc and dorsal longitudinal ligaments ventrally, the articular process (facet) joint capsules laterally, and the ligamentum flavum (interarcuate ligament) and interspinous ligaments dorsally.

SURGICAL TECHNIQUE

Dorsal laminectomy is used to access the cauda equina, with or without removal of articular process tissue (foraminotomy or facetectomy). Crucial to the performance of a dorsal laminectomy in this region of the spine is proper positioning. The patient should be positioned in a manner that opens the L7–S1 space. The pelvic limbs are flexed and positioned along the patient's abdomen (Fig. 42.3).

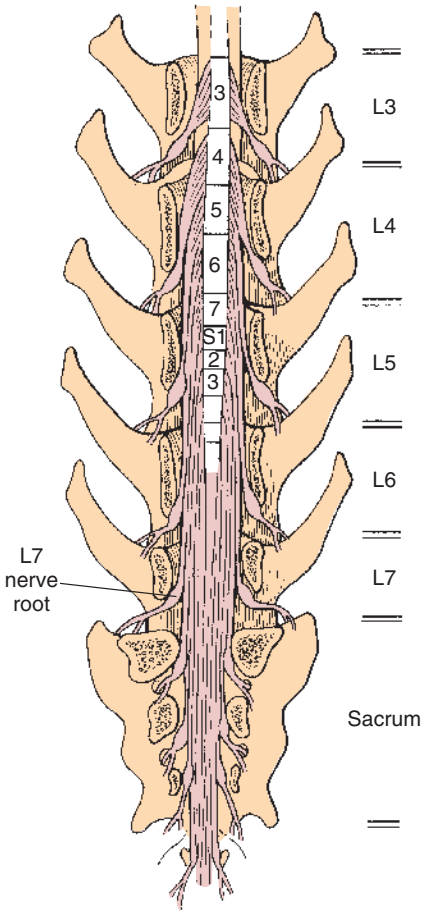

FIG. 42.2 Anatomic relationship of vertebral bodies to spinal cord termination and cauda equina in a medium- to large-breed dog.

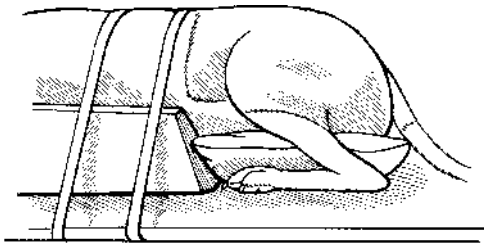

FIG. 42.3 Positioning patients with the pelvic limbs tucked under the abdomen helps accentuate the L7–S1 interarcuate space.

Dorsal Laminectomy

Position the patient in sternal recumbency with the pelvic limbs pulled cranially, as shown in Fig. 42.3. Maintain this position with sandbags, towels, a deflated air cushion, or a V trough. Using the iliac crests and L6 dorsal spinous process as landmarks, create a midline incision from the dorsal spinous process of L5 to the end of the sacral crest (base of the tail). Sharply incise through subcutaneous tissue and fat to reach the thick lumbodorsal fascia. Incise this fascial layer on midline and around the dorsal spinous processes of interest with a No. 11 blade, Mayo scissors, or a combination of the two. Elevate the multifidus lumborum (cranially) and sacrocaudalis dorsalis medialis (caudally) muscles from the dorsal

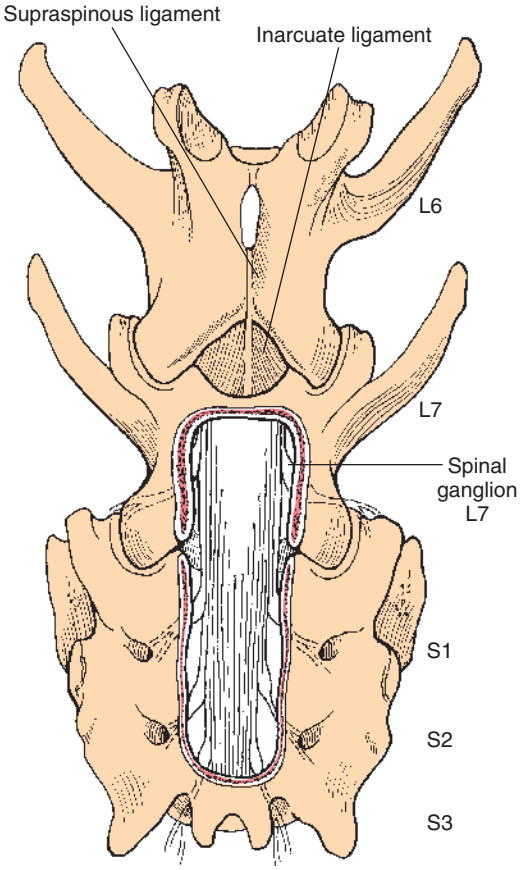

FIG. 42.4 L7–S1, S2 dorsal laminectomy provides exposure of the filum terminale and cauda equina.

spinous processes and median sacral crest using either Freer periosteal elevators (small dogs and cats) or Army-Navy osteotomes (large dogs). Continue this periosteal elevation to expose the dorsal lamina of L7 and the sacrum. Exposure of the L7–S1 junction is facilitated by also exposing L6–L7. Fully expose the articular processes of L7–S1 laterally to the level of the medial aspect of the ilium on each side. Place Gelpi retractors cranially and caudally. Sharply excise the interarcuate ligament between L7 and S1. Identify the interarcuate space of L7–S1 and carefully excise ligamentum flavum tissue with a No. 11 blade and a nontoothed Bishop-Harmon forceps so that the bone edges of caudal L7 and cranial S1 are visualized. Remove the dorsal spinous process of L7 and the cranial half of the median sacral crest with a bone cutter and/or rongeur. Use a high-speed air drill to create the dorsal laminectomy defect, drilling through outer cortical and inner cancellous bone to reach the inner cortical layer. The lateral aspects of the L7 dorsal lamina are thickest, and the dorsal lamina of the sacrum is considerably thinner than that of L7.

Once the inner cortical bone is soft enough, remove it with fine-tipped Lempert rongeurs and/or flake it off with the spatula end of a Gross ear hook and spoon. Remove any remaining periosteum and/or interarcuate ligament (ligamentum flavum) and overlying epidural fat to expose the cauda equina (Fig. 42.4). In some chronic cases of DLSS, the ligamentum flavum and/or endosteum may be adhered to the nerve roots; in this case, carefully dissect the connective tissue off the nerve roots with a No. 11 blade. Using a probe (e.g., Gross ear hook and spoon), feel under the edges

of the laminectomy defect, especially laterally and in the region of each intervertebral foramen. If compression of the L7 nerve root is still apparent after dorsal laminectomy and removal of compressive annulus tissue, perform a facetectomy or foraminotomy.

Facetectomy and Foraminotomy

Perform a facetectomy by sharply incising and removing the articular process joint capsule tissue of L7–S1, then drilling off the facets from dorsal to ventral using a high-speed air drill. Remove the most ventral aspect of the facets with a fine-tipped Lempert rongeur to avoid ensnaring the L7 nerve root with the burr. To perform a foraminotomy, visually bisect the dorsoventral length of the L7–S1 articular facets. Using a small (1- to 2-mm) burr, drill a longitudinal trough through the facet tissue at this bisection and then snip off the ventral layer of bone (dorsal limit of the intervertebral foramen) with a fine-tipped Lempert rongeur. An angled burr guard is recommended for this procedure. Attempting a foraminotomy by drilling within the intervertebral foramen is not recommended for fear of damaging the L7 nerve root. *Close the site routinely. To help prevent seroma formation, use an interrupted subcuticular pattern for closure.*

HEALING OF THE CAUDA EQUINA

The nerve roots of the cauda equina are more resistant to injury compared with spinal cord parenchyma and respond to injury similar to the response of peripheral nerves. Nerve injury is typically classified according to severity. From least severe to most severe, nerve injury is classified as class I (neurapraxia), class II (axonotmesis), and class III (neurotmesis) (Table 42.1). Class I injury or neuropraxia refers to a transient lack of nerve function, with little or no structural damage to the axons or their supportive connective tissue structures. This temporary dysfunction may be due to ischemia (no structural damage) and/or mild paranodal demyelination. The degree of motor and proprioceptive dysfunction is variable, but nociceptive function is preserved for the most part (large-diameter axons are preferentially affected). Spontaneous recovery is expected within days to a month, depending on the degree of demyelination. Neurogenic muscle atrophy is unlikely, as the axons are structurally intact. With class II injury (axonotmesis), some or all of the axons of the nerve are disrupted structurally, but the connective tissue support (e.g., Schwann cell basal lamina, endoneurium) remains intact. These axons can regrow along the connective tissue scaffold. Substantial motor, proprioceptive, and nociceptive dysfunction is expected, the extent of which depends on the number of axons damaged. Neurogenic muscle atrophy is likely with this class of injury. Class III injury or neurotmesis denotes complete severance of the axons of the nerve, as well as the connective tissue support. These axons will not regrow (no guiding scaffold) without surgical intervention. Complete motor, proprioceptive, and nociceptive (i.e., no pain perception) dysfunction occurs with this class of injury. Neurogenic muscle atrophy is to be expected. A severe class II injury may be clinically indistinguishable from a class III injury. In addition to the extent of nerve injury, the length of nerve required to regenerate affects prognosis. Axons grow at a rate of 1 to 4 mm per day. In people with nerve injuries, muscle motor end-plate degeneration tends to occur if the damaged nerve does not reestablish contact with the target muscle within 18 months. Therefore proximal nerve injuries have more guarded prognoses than distal injuries, even if axonal regeneration occurs.

SUTURE MATERIALS AND SPECIAL INSTRUMENTS

Suture material and special instruments for cauda equina surgery are the same as those used for thoracolumbar spinal surgery (see pp. 1374 and 1414).

POSTOPERATIVE CARE AND ASSESSMENT

Postoperative care and assessment are similar to that described for thoracolumbar spinal surgery patients. Short leash walks are allowed after surgery for dogs with DLSS, but longer walks, running, or going up and down stairs may lead to seroma formation. Patients with fracture/luxation at the lumbosacral area should have minimal exercise for the first 2 to 3 weeks after surgery (short walks to urinate and defecate) and gradually return to normal activity over a 2- to 3-month period. Appropriate bladder care and prevention of fecal soiling of the perineal region are necessary in cauda equina patients that have lost, or partially lost, urinary or fecal continence, respectively.

COMPLICATIONS

Severe complications are not commonly encountered in dogs undergoing surgery for cauda equina disorders. As in any spinal

TABLE 42.1 Causes and Characteristics of Nerve Injuries

Nerve Injury Classification	Causes	Characteristics
Class I (neurapraxia)	Ischemia (no structural damage) and/or mild paranodal demyelination	Transient lack of nerve function Little to no structural damage to axons Variable motor and proprioceptive dysfunction Nociceptive function is generally preserved Spontaneous recovery within days to a month
Class II (axonotmesis)	Mainly seen in crush injury	Structural disruption of axons Connective tissue support remains intact Axons may regrow along connective tissue scaffold Substantial motor, proprioceptive, and nociceptive dysfunction Neurogenic muscle atrophy
Class III (neurotmesis)	Occurs with severe contusion, stretch, or laceration	Complete severance of axons of the nerve and connective tissue Axons will not regrow without surgical intervention Complete motor, proprioceptive, and nociceptive dysfunction Neurogenic muscle atrophy

cord surgery, neurologic worsening that results from manipulation of neural tissue at surgery is always a risk, albeit a small one. The most common complication following surgery of the cauda equina is development of a seroma at the surgery site. Current recommendations are to apply a warm compress to the seroma region several times per day. This usually resolves the problem. Intermittent or continuous drainage is also an option but may predispose the patient to developing a wound infection. In patients with LMN bladder dysfunction, recurrent urinary tract infections are a probable complication after surgery, and meticulous attention to bladder emptying must be paid to minimize this problem. Complications possible with trauma patients with implants include implant failure, inappropriate implant placement (e.g., into the vertebral canal), and implant-associated infection.

SPECIAL AGE CONSIDERATIONS

There are few clinically important age considerations associated with surgery at the cauda equina. In immature patients with traumatic fracture/luxation at L7–S1, the surgeon should be aware that the implant-holding capacity of immature bone is inferior to that of an adult. Older dogs are more likely to develop discospondylitis than younger dogs, so one should be aware that some older patients with suspected DLSS may have discospondylitis as a contributing or primary condition.

SPECIFIC DISEASES

DEGENERATIVE LUMBOSACRAL STENOSIS

DEFINITIONS

DLSS is a compressive disorder of the cauda equina caused by protrusion of supportive tissues (disc annulus, articular process joint capsule, interarcuate ligament) into the vertebral canal. Compromise of one or both L7–S1 intervertebral foramina, with subsequent compression of the L7 nerve root(s) is also a major component of this disorder. **Transitional vertebrae** are malformed vertebrae that possess shape characteristics of two different vertebral types. The L7 vertebra in dogs with DLSS often has a segmented appearance like the sacrum; this is called *sacralization* of the lumbar vertebra. The sacrum in these dogs sometimes has characteristics of a lumbar vertebra (e.g., transverse process unilaterally or bilaterally); this is called *lumbarization* of the sacrum.

GENERAL CONSIDERATIONS AND CLINICALLY RELEVANT PATHOPHYSIOLOGY

The pathogenesis of DLSS involves type II degeneration and subsequent protrusion of the L7–S1 intervertebral disc into the vertebral canal (Fig. 42.5). There are often other degenerative changes at the lumbosacral junction, indicative of chronic instability. Ventral spondylosis is often appreciated at the lumbosacral junction in these patients, but by itself, this radiographic finding has little clinical significance. Some of the degenerative changes, other than disc protrusion, that may lead to compression of the cauda equina include collapse of the intervertebral disc space at L7–S1 and subluxation of the L7–S1 articular facets (articular processes); the craniodorsal aspect of the sacrum may become displaced ventral to the caudodorsal aspect of the L7 vertebra; hypertrophy and folding inward (ventrally) of the

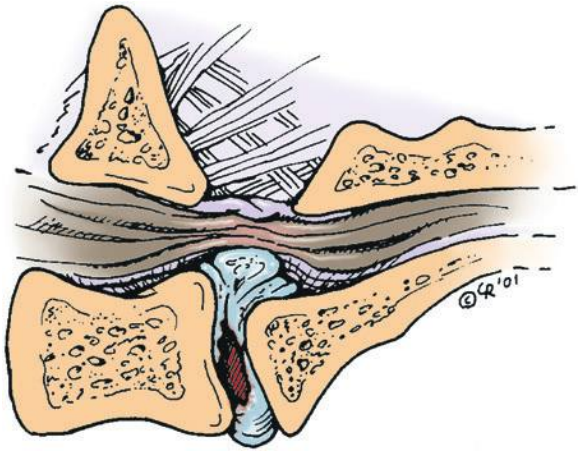

FIG. 42.5 Schematic illustration depicting a protruding disc at the L7–S1 intervertebral disc space.

interarcuate ligament (ligamentum flavum) located between the dorsal laminae of L7 and S1 may occur; and hypertrophy of soft tissue structures (e.g., joint capsule) as well as osteophyte formation associated with the L7–S1 articular processes (facets) may be observed. It has been shown that extension of the lumbosacral junction (lordosis) results in a significant decrease in the volume of the L7–S1 intervertebral foramina, compared with neutral and flexed positions; flexion of the lumbosacral junction has the opposite effect, increasing the volume of the L7–S1 foramina. In one volumetric computed tomography (CT) study, the dynamic narrowing of the L7–S1 intervertebral foramina in extension was more pronounced in German shepherd dogs with clinical features of DLSS compared with German shepherd dogs without clinical evidence of DLSS.[3]

Reasons for the chronic degenerative processes involved in DLSS are unknown. In German shepherds (as well as other large-breed dogs), the presence of transitional vertebrae at the lumbosacral junction has been associated with development of DLSS. Dogs with transitional lumbosacral vertebrae are approximately eight times more likely to develop DLSS than dogs without such anomalous vertebrae. Dogs with transitional lumbosacral vertebrae also develop clinical signs of DLSS 1 to 2 years earlier than dogs with lumbosacral stenosis that do not have these abnormal vertebrae. In addition to having a high incidence of transitional vertebrae at the lumbosacral junction, German shepherds have been shown to have different orientation of vertebral articular processes (facets) in the caudal lumbar and lumbosacral regions of the spinal column and a greater degree of facet joint tropism in this region, compared with other large-breed dogs. Facet joint tropism means an asymmetry in the angle of orientation between left and right articular processes (facets) at a given level of articulation. These anatomic differences, as well as the propensity for German shepherds to have transitional lumbosacral vertebrae, may partly explain the breed prevalence for DLSS.

DIAGNOSIS

Clinical Presentation

Signalment

This is a common disease syndrome that typically affects adult (usually middle-aged to older), large-breed dogs. According to

some reports, there is a male predilection for this disease. The German shepherd appears to be particularly predisposed to DLSS.

History

The majority of dogs with DLSS have chronic (weeks to months) histories of pain and unilateral or bilateral pelvic limb lameness, with or without pelvic limb weakness. Pain is often localized to the back, but in many cases the owners are not sure if the pain is associated with the back or the pelvic limbs. Other historical findings include difficulty rising, inability or unwillingness to climb stairs or exercise, scuffing of the toenails of the pelvic limbs, muscle atrophy in the caudal thigh region, urinary and/or fecal incontinence, and/or abnormal (usually low) tail carriage with decreased tail movement and biting/chewing at the tail base and/or paws of the pelvic limb.

Physical Examination Findings

Clinical signs are variable, but lumbosacral pain is an early and consistent finding. Pain may be manifested in a number of ways, such as reluctance to rise or sit, and unilateral or bilateral pelvic limb lameness. Pain and lameness may be acute or chronic and may be persistent or episodic. These clinical signs may be misinterpreted as being due to orthopedic disease, most notably hip dysplasia. Many of these dogs have radiographic evidence of hip dysplasia, making this a particularly easy trap to fall into when the only obvious clinical sign of an abnormality is pain and/or pelvic limb lameness. If untreated, clinical signs of dysfunction may progress to proprioceptive loss in the pelvic limbs, voluntary motor weakness (in the distribution area of the sciatic nerve), and urinary/fecal incontinence, often in that order. Deficient pelvic limb withdrawal reflexes are most apparent at the hock level in cases of DLSS; flexion at the hip and stifle regions often appears normal. Although typically indicative of progressively severe cauda equina compression, urinary and/or fecal incontinence occasionally comprises the initial primary clinical complaint in cases of DLSS. Careful palpation of the lumbosacral area, including lordosing the caudal spine while pressing on the lumbosacral area, will usually elicit a pain response in affected patients. Most dogs afflicted with this disease also have obvious deficits on proprioceptive positioning tests of the pelvic limbs.

Diagnostic Imaging

The definitive diagnosis of DLSS is made by imaging of the lumbosacral area and demonstrating compression of the cauda equina. Magnetic resonance imaging (MRI) (Fig. 42.6) and CT (Fig. 42.7) are the imaging procedures of choice for DLSS, with all other imaging procedures rapidly becoming historical in nature. For MRI evaluation of the L7–S1 intervertebral foramina, oblique parasagittal imaging planes have been recommended over standard parasagittal planes to more accurately evaluate the dimensions of the foramina.[4] Although degenerative changes at the lumbosacral junction (e.g., spondylosis, malalignment of the sacrum with the L7 vertebra) may often be appreciated on plain radiographs of the region, additional imaging is necessary to demonstrate cauda equina compression. A number of procedures have been advocated in the past, including myelography, epidurography, vertebral sinus venography, and discography. Because the terminal thecal sac (subarachnoid space) of the spinal cord in large-breed dogs often ends cranial to the lumbosacral junction, myelography may not consistently provide useful information. *Vertebral sinus* venography is considered to be both a technically difficult and unreliable imaging procedure. *Discography* is an accurate imaging method for DLSS but provides information primarily limited to the intervertebral disc. *Epidurography* is also considered to be a relatively accurate contrast procedure to identify cauda equina compression. Combination discography/epidurography has also been demonstrated to be a useful diagnostic imaging method for DLSS. There is evidence that dogs without clinical signs of disease at the cauda equina may have imaging findings consistent with a diagnosis of DLSS and that the degree of cauda equina compression evident on imaging does not necessarily correlate with disease presence or severity. It is apparent that evidence on imaging studies consistent with a diagnosis of DLSS may be an incidental finding in some dogs. It is also apparent that the extent of cauda equina compression appreciated on such imaging studies is not necessarily indicative of disease severity in patients that exhibit clinical signs of DLSS. Middle-aged to older, large-breed dogs often demonstrate hyperesthesia on palpation of the lumbosacral junction during a neurologic examination that has nothing to do with the presenting complaint or ultimate diagnosis. In other words, some dogs with DLSS may have subtle or inapparent clinical signs that can only be elicited on palpation. It is imperative to realize that focusing on the lumbosacral junction in some patients may lead to overlooking another spinal disorder that is primarily responsible

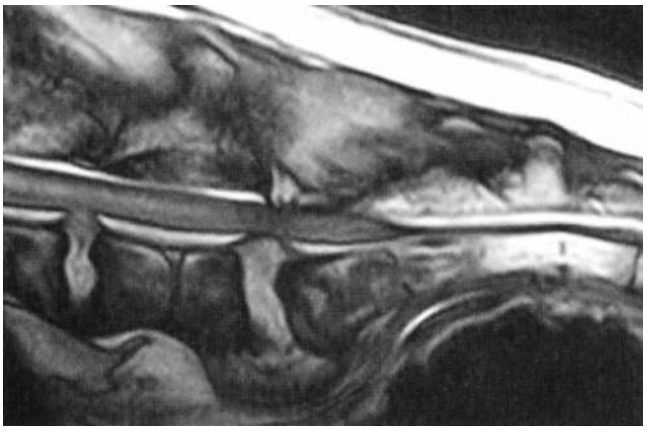

FIG. 42.6 Sagittal magnetic resonance image (T2 weighted) of a dog with degenerative lumbosacral stenosis. There is protrusion at both the L6–L7 and L7–S1 intervertebral disc spaces.

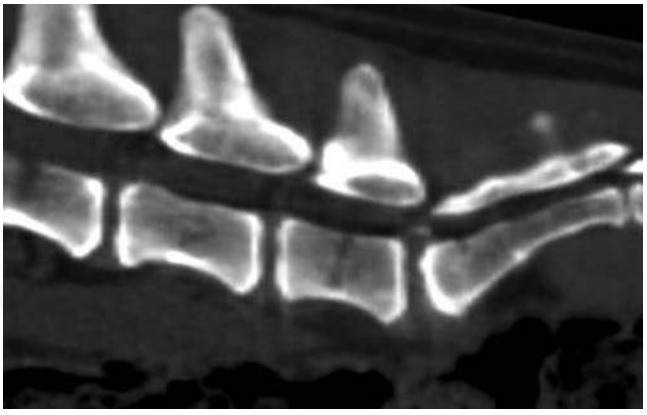

FIG. 42.7 Midsagittal computed tomography reconstructed image of a dog with degenerative lumbosacral stenosis.

for the clinical deficits. In patients with subtle deficits (e.g., pelvic limb proprioceptive deficits and spinal hyperesthesia), it may be worthwhile to have survey image of the thoracolumbar region (e.g., T2-sagittal magnetic resonance survey) to ensure that the lumbosacral lesion is not an incidental finding. Concurrent electromyography performed on the epaxial, tail, and pelvic limb musculature may improve the accuracy of diagnosis with the various imaging modalities. Tibial nerve somatosensory evoked potentials have also been shown to be abnormal in dogs with clinical evidence of DLSS.[5]

Laboratory Findings

Laboratory findings in dogs with DLSS are generally nonspecific. A stress leukogram may be evident in patients who have received glucocorticoid therapy.

DIFFERENTIAL DIAGNOSIS

Differential diagnoses for DLSS include infectious/inflammatory disease (e.g., discospondylitis, vertebral osteomyelitis), neoplasia (vertebral or soft tissue), and trauma (fracture/luxation). Hip dysplasia can cause many signs similar to DLSS, but this can be ruled out as a sole explanation for the patient's clinical signs with a neurologic examination.

MEDICAL MANAGEMENT

Medical therapy for DLSS consists of enforced rest and antiinflammatory/analgesic medication, and is often recommended for dogs with signs of hyperesthesia only. Nonsurgical therapy is often either transiently effective or ineffective for this disease. However, in one retrospective study with long-term follow-up (mean and median of approximately 3 years), 55% of medically managed dogs with DLSS had successful outcomes.[6]

SURGICAL TREATMENT

In patients with neurologic deficits, or patients for whom pain is refractory to nonsurgical management, surgery is the preferred mode of therapy. Surgery usually consists of a dorsal laminectomy over the L7–S1 interspace, sometimes combined with removal of hypertrophied soft tissue (e.g., annular disc material). It should be noted that there is no evidence that resection of disc material (annulectomy and partial discectomy) improves clinical outcomes over dorsal laminectomy alone, but that there is evidence from cadaver studies that dorsal laminectomy combined with discectomy results in significant destabilization of the L7–S1 articulation, including dynamic collapse of the intervertebral foramina.[7,8] Enlargement of the L7–S1 intervertebral foramen (foraminotomy) or removal of the articular facets (facetectomy) may also be required if compression of the L7 nerve root is appreciated. Many surgeons do not advocate routine surgical stabilization of the lumbosacral joint, but this may be advisable in some cases (e.g., bilateral facetectomy). There are numerous published techniques for stabilization of the lumbosacral region, some of which are discussed under Trauma. Recently, a minimally invasive transilial vertebral blocking (MTV) procedure has been described for treatment of dogs with DLSS. In this technique, the patient is secured with the lumbosacral joint in a flexed position, and a premeasured transilial bolt is fluoroscopically (C-arm) placed via a detachable target pin (using the L7 dorsal spinous process as a buttress), fixing the L7–S1 space in distraction (Fig. 42.8). In a prospective evaluation of 59 dogs with DLSS treated with the MTV procedure, significant increases in L7–S1 end-plate distance and the mean areas of the L7–S1 foramina were documented via CT measurements.[9]

Preoperative Management

Preoperative management for cauda equina surgery is discussed on p. 1428.

Anesthesia

Anesthesia for patients undergoing spinal surgery is discussed on p. 1366.

Surgical Anatomy

The pertinent surgical anatomy of the lumbosacral area and cauda equina is discussed on pp. 1404 and 1428.

Positioning

Positioning for dorsal laminectomy at L7–S1 is discussed on p. 1429.

SURGICAL TECHNIQUE

The surgical techniques for dorsal laminectomy at L7–S1, facetectomy, and foraminotomy are described on pp. 1428 to 1430. Removal of protruding annulus fibrosus may be indicated in some instances. *To remove protruding dorsal annulus fibrosus of the L7–S1 disc, gently retract the nerve roots medial to the L7 nerve root on one side to expose the disc on that side. Use 25-gauge needles to act as retractors by placing the needles into the disc, holding the needle hub with a straight Mosquito hemostat during insertion (Fig. 42.9). Cut a wedge of annulus out of the disc using a sharp No. 11 blade, and remove the wedge with either straight Mosquito hemostats or the tips of a Lempert rongeur. Remove the needles and repeat the procedure on the opposite side. Control venous sinus hemorrhage, if necessary, as described on p. 1366.*

SUTURE MATERIALS AND SPECIAL INSTRUMENTS

Suture material and special instruments for dorsal laminectomy or foraminotomy/facetectomy at the lumbosacral junction are the same as those used for thoracolumbar spinal surgery (see pp. 1374 and 1414).

COMPLICATIONS

Complications of surgery at the lumbosacral junction are discussed on p. 1430.

PROGNOSIS

The prognosis for functional recovery from this disorder is generally good to excellent with surgical intervention and fair for medical treatment alone (see Medical Management). Successful outcomes after surgery have been reported in the majority of cases. It appears that although improvement in continence may occur in dogs with presurgical fecal and/or urinary incontinence (over weeks to months following surgery), resolution of incontinence is not likely to occur in most cases. Incontinence fails to resolve after decompressive surgery in half to two-thirds of cases. Improvement or resolution of incontinence has been shown to be much less likely in dogs that have been incontinent for

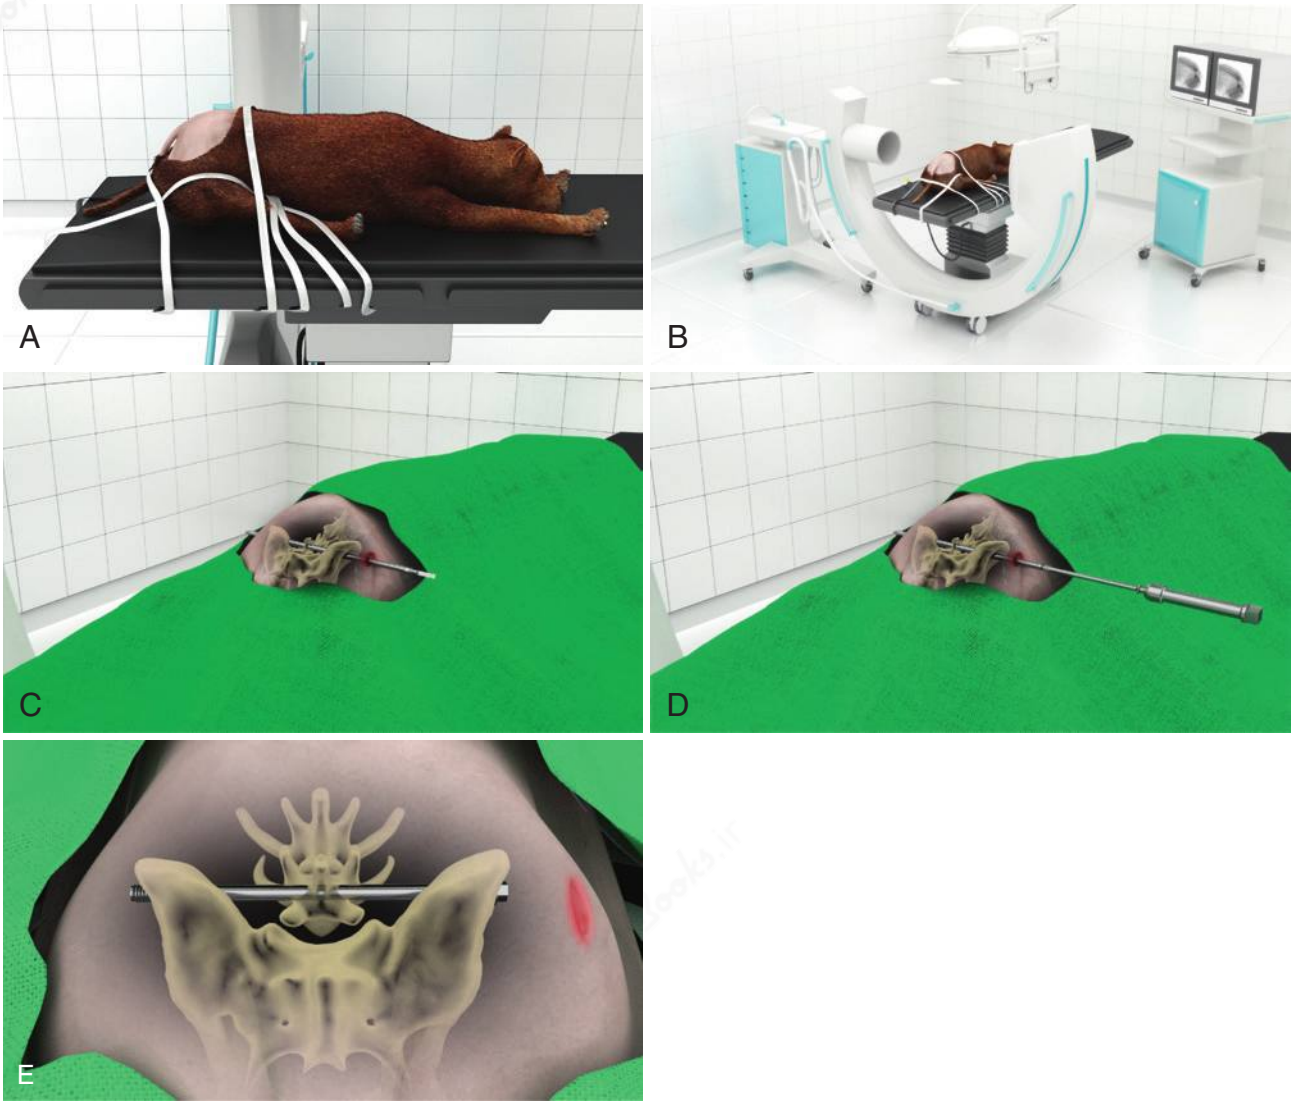

FIG. 42.8 Schematic steps of the minimally invasive transilial vertebral blocking procedure. (A) Positioning the patient. (B) Positioning the C-arm (fluoroscope). (C) Drilling the target pin (through a skin incision). (D) Target pin in place, connected to implant. (E) Implant in position, target pin disconnected. (From Müller F, Schenk HC, Forterre F. Short-term and long-term effects of a minimally invasive transilial blocking procedure on the lumbosacral morphometry in dogs measured by computed tomography. *Vet Surg.* 2017;46[3]:354–366.)

more than 1 month, compared with those that have shorter histories of incontinence. Recurrence rates for DLSS vary between 3% and 18%. Recurrence is probably more likely in very active dogs (i.e., working dogs). For the 39 dogs in the prospective MTV study available for long-term follow-up (1 year), all had improved by at least one neurologic grade (using a three grade scoring system: mild, moderate, severe dysfunction); in addition, 78% of all owners indicated via questionnaire that they would recommend the procedure.[9]

NEOPLASIA

DEFINITIONS

Neoplasms involving the lumbosacral vertebra and nerve roots are similar to those of the cervical and thoracolumbar regions (see pp. 1396 and 1429). As in other areas of the spine, tumors of the cauda equina can be primary (e.g., malignant nerve sheath tumor) or secondary (e.g., L7 or S1 vertebral body tumor).

GENERAL CONSIDERATIONS AND CLINICALLY RELEVANT PATHOPHYSIOLOGY

Tumors of the lumbosacral vertebrae and nerve roots are rare. Tumor type, location (e.g., spine, surrounding soft tissue, or nerve root), and classification (e.g., extradural, intradural-extramedullary, or intramedullary) are similar to neoplasms of the cervical, thoracic, and lumbar spine (see pp. 1396 and 1429). Regardless of tumor type or location, once the encroaching mass becomes large enough to cause cauda equina compression and ischemia, any of the neurologic signs associated with DLSS or fracture/luxation may occur.

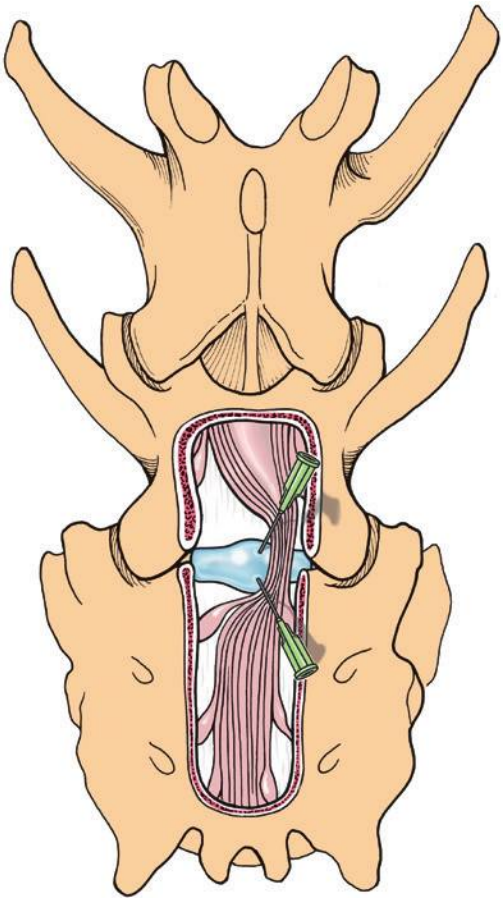

FIG. 42.9 Retract nerve roots laterally with care to facilitate excision of hypertrophied dorsal annulus fibrosus. Use needles placed into the disc to maintain nerve root retraction.

DIAGNOSIS

Clinical Presentation

Signalment

There is no sex or breed predilection for patients with tumors of the lumbosacral area or cauda equina. Generally, patients with spinal tumors are older than 5 years of age. An exception is solitary or multiple cartilaginous exostoses, which usually occur in patients less than 1 year of age. Another exception is lymphosarcoma, which often affects young animals.

History

History depends on the specific location of the neoplasm as well as both the degree and time course of cauda equina compression. Patients may present with variable degrees of back pain, with or without LMN ambulatory paraparesis. Patients with nerve root tumors of the cauda equina usually have a chronic history of pelvic limb lameness (i.e., monoparesis from root signature). As the tumor enlarges and compresses more of the cauda equina, paraparesis becomes evident. Patients with vertebral body or surrounding soft tissue (extradural) tumors may have an acute history of back pain and ambulatory or nonambulatory paraparesis. Careful historical examination may reveal previous (e.g., weeks to months) subtle back pain or pelvic limb lameness.

FIG. 42.10 Lateral radiograph of a dog with L7–S1 intervertebral foramen lysis *(arrow)* suggestive of nerve root tumor.

Physical Examination Findings

Physical and neurologic examination findings vary depending on anatomic location of the tumor (e.g., spine, paraspinal soft tissue, nerve root), degree of nerve root compression/ischemia, specific nerve roots involved, and associated secondary effects (e.g., paraneoplastic syndrome). Generally, patients present with any combination of LMN signs associated with cauda equina compression.

Diagnostic Imaging

Radiographic findings suggestive of vertebral neoplasia include vertebral body osteolysis and/or osteoproduction. These findings are generally associated with primary bone tumors (e.g., osteosarcoma, chondrosarcoma, fibrosarcoma). Lysis of an intervertebral foramen suggests a nerve root tumor (e.g., neurofibroma, meningioma) (Fig. 42.10). Diagnosis of neoplasia affecting the lumbosacral area and cauda equina is best accomplished using MRI (Fig. 42.11) or CT.

Laboratory Findings

Laboratory findings are generally normal or reflect paraneoplastic syndromes (e.g., hypercalcemia, monoclonal gammopathy). Patients with severe back pain and those treated with corticosteroids may have a stress leukogram.

DIFFERENTIAL DIAGNOSIS

Differential diagnoses for cauda equina dysfunction include DLSS; fracture/luxation; discospondylitis; vertebral osteomyelitis; fibrocartilaginous emboli; neoplasia of the spine, surrounding soft tissue, or nerve roots; chronic degenerative disc disease; herniated intervertebral disc extrusion; or congenital lumbosacral stenosis. Hip dysplasia can cause many signs similar to cauda equina disease, but this can be ruled out as a sole explanation for the patient's clinical signs with a neurologic examination.

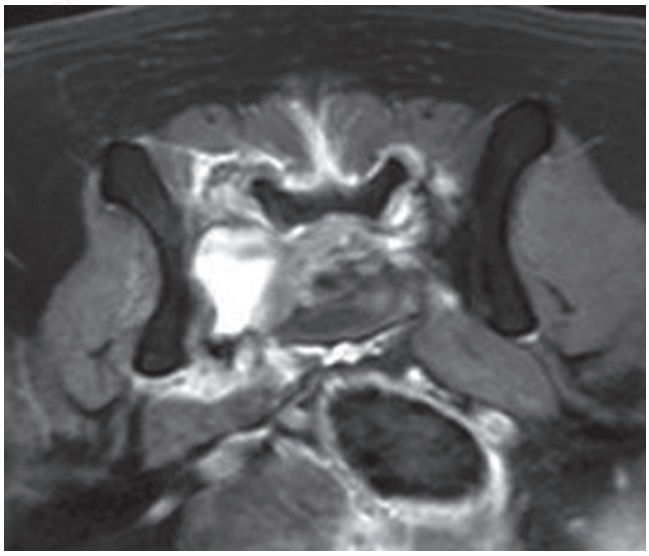

FIG. 42.11 Axial magnetic resonance image (T1 weighted with contrast) of the lumbosacral region of a dog. A large mass (chondrosarcoma) invading the vertebral canal is evident.

MEDICAL MANAGEMENT

Medical management is directed at both the primary lesion and secondary effects of the tumor. Glucocorticoid therapy is generally not recommended for primary treatment of nerve root injury. With most lumbosacral neoplasms, definitive medical treatment requires surgical exposure and incisional or excisional biopsy to determine tumor type and to plan appropriate adjunct chemotherapy, immunotherapy, irradiation, or combination therapy.

SURGICAL TREATMENT

Surgical treatment objectives include the definitive diagnosis of cauda equina compression (e.g., neoplasia, herniated disc, abscess); decompression and mass removal; incisional or excisional biopsy (wide surgical excision is preferred if possible); tumor staging, and, if necessary, spinal stabilization. If wide surgical excision creates spinal instability, stabilization is performed as described on p. 1438. Definitive histologic diagnosis is used to plan adjunct chemotherapy, radiation, or combination therapy.

Preoperative Management

Patients are given IV fluids before surgery. Preoperative management of patients with lumbosacral neoplasia is similar to that described for patients with any lumbosacral compressive lesion (see p. 1428). Preoperative steroids are not indicated because they do not protect nerve roots. If lumbosacral instability is suspected, care should be taken to support the pelvis during manipulations.

Anesthesia

Suggested anesthetic regimen for use in patients with spinal disorders are discussed on p. 1366.

Surgical Anatomy

The pertinent surgical anatomy of the lumbosacral area and cauda equina is discussed on pp. 1408 and 1428.

Positioning

Exposing neoplasms of the lumbosacral region generally requires a dorsal approach and wide dorsal laminectomy with unilateral or bilateral facetectomy and foraminotomy. If stabilization is needed, a dorsal approach is also recommended. Therefore position the patient in sternal recumbency with the hind legs tucked under the abdomen to gently flex the lumbosacral junction (see Fig. 42.3). This position facilitates exposure of the dorsal interarcuate space.

SURGICAL TECHNIQUE

Malignant Nerve Sheath Tumors

Tumors involving nerve roots of the cauda equina as they course through the lumbosacral vertebral canal are best approached using dorsal laminectomy, facetectomy, and foraminotomy as described on pp. 1428 to 1430. It is important to identify the specific nerve root or roots to be resected, and to have knowledge of the effect of resection on the patient's neurologic function. Neurologic deficits created by single or multiple nerve root resection may incapacitate the patient to an unacceptable degree. In such cases, biopsy for histopathologic diagnosis and adjunct medical management may be indicated.

NOTE If possible, excise the tumor so as to include 2 cm of adjacent, normal-appearing tissue.

Enter the vertebral canal by carefully elevating the inner periosteal layer with a dental or iris spatula and ophthalmic forceps. Remove any remaining epidural fat. Identify cauda equina nerve roots on the floor of the vertebral canal. Use a probe (e.g., Gross ear hook and spoon) to carefully follow the S1 and L7 nerve roots as they course along the floor of the vertebral canal. Identify the L7 nerve root as it lies against the caudal aspect of the L7 pedicle, and follow it as it disappears through the L7–S1 intervertebral foramen. Carefully examine each nerve root for evidence of diffuse enlargement or localized bulging. If the lesion is resectable, identify the nerve root involved, carefully cauterize the root cranial to the lesion using bipolar cautery, transect the root with a No. 11 scalpel blade, and carefully elevate the transected portion of the root. Follow the affected nerve root caudal to the lesion and complete the resection as described previously. Reexamine the cauda equina to rule out multiple nerve root tumors. Lavage the surgical wound and close tissues routinely.

Tumors Involving the Vertebral Body or Surrounding Soft Tissues

Tumors involving the vertebral body or surrounding soft tissues are best approached via dorsal laminectomy as described on p. 1429. *Perform a dorsal laminectomy to remove affected bone and provide cauda equina decompression. If bony involvement is extensive and nonresectable, use a trephine or bone curette to biopsy affected bone and perform a dorsal laminectomy to provide cauda equina decompression. If surrounding soft tissue structures are involved, biopsy representative areas. If neoplastic tissue is cavitated or abscessed, obtain samples for anaerobic and aerobic culture and susceptibility testing. If spinal instability is diagnosed or occurs as a result of decompression, perform spinal stabilization as described on p. 1438.*

POSTOPERATIVE CARE AND ASSESSMENT

Patients with neoplasia of the lumbosacral spine should be monitored postoperatively in a similar fashion as patients with other lumbosacral spinal disorders. In general, strict confinement, analgesics as needed, short walks using an abdominal sling, frequent urinary bladder evacuation, and daily neurologic examinations are indicated. Long-term monitoring and adjunct medical therapy are dependent on tumor type and surgical margins.

PROGNOSIS

Prognosis depends on tumor type (biologic activity), surgical margins (percent of tumor resection), and sensitivity to adjunct therapy (chemotherapy, radiation therapy, or combination therapy). Malignant extradural neoplasms tend to have an unfavorable prognosis, benign extradural neoplasms have a favorable prognosis, and extradural-intramedullary neoplasms (e.g., mixed compartment tumors such as malignant nerve sheath tumors) have a guarded to unfavorable prognosis.

TRAUMA

DEFINITIONS

Traumatic or pathologic disruption of osseous and supporting soft-tissue structures of the caudal lumbar, sacral, and first caudal vertebrae (e.g., L6–Cd1 through L6–Cd5) may result in vertebral fracture or luxation and subsequent nerve root compression (i.e., cauda equina). Fractures of the lumbosacral spine are also called a *broken back, caudal lumbar fractures,* and *vertebral fractures.*

GENERAL CONSIDERATIONS AND CLINICALLY RELEVANT PATHOPHYSIOLOGY

Fractures and luxations of the caudal lumbar vertebra, lumbosacral articulation, sacrum, and caudal vertebrae generally result from direct flexional trauma to the hindquarters. Fractures are usually oblique or short oblique involving the vertebral body of L6 or L7 and may be accompanied by luxation of articular facets. Cranioventral displacement of the caudal segment typically occurs because of muscular forces acting on the sacrum and pelvis, along with the weight of the pelvic mass (Fig. 42.12). Lumbosacral fractures are fairly common due to the static-kinetic relationship of the relatively fixed sacrum to the mobile caudal lumbar and caudal vertebral bodies. The most common cause of fracture/luxation is vehicular trauma. The spinal cord typically terminates in the body of L6 in dogs; therefore neurologic signs are usually associated with trauma to nerve roots of the cauda equina instead of the spinal cord. In cats, the spinal cord often terminates over the body of S1. Because of the ability of nerve roots to resist traumatic injury, substantial displacement of the fracture or luxation may still leave the patient neurologically intact. Conversely, fractures or luxations may occur in which severe displacement of the fracture/luxation segments causes tethering or avulsion of nerve roots and will occasionally produce trauma to the caudal spinal cord; neurologic deficits in these patients are often profound. As mentioned previously in this chapter, stabilization of the lumbosacral junction may be warranted in some cases of DLSS as an adjunct to dorsal laminectomy with or without discectomy. The procedures discussed in this section for trauma to the lumbosacral region can be adapted to cases of DLSS.

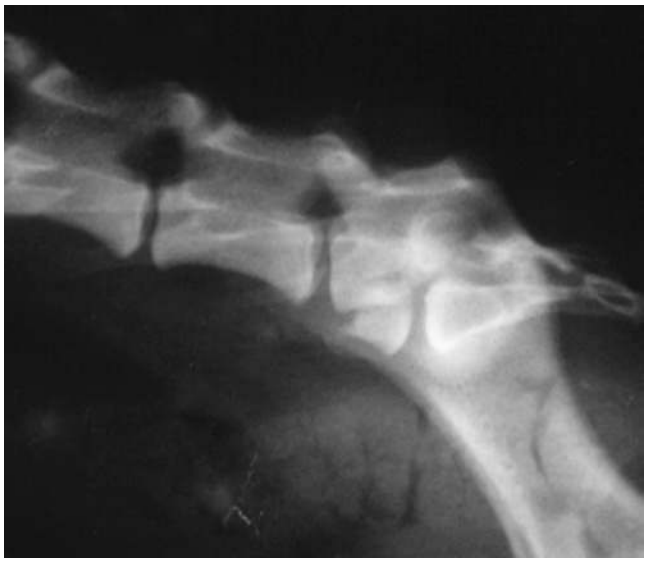

FIG. 42.12 Lateral radiograph of a dog with an L7 fracture. Notice the cranioventral displacement of the sacrum, pelvis, and L7 fracture fragment, which is typical with these fractures.

DIAGNOSIS

Clinical Presentation

Signalment

There is no specific age, sex, or breed predilection for canine or feline lumbosacral fracture/luxation. However, dogs are more likely to sustain this injury than cats, and there is a trend of dogs less than 3 years of age being affected more often.

History

The majority of dogs and cats with lumbosacral fracture/luxation have a history of recent vehicular trauma. Patients generally present with varying degrees of lumbar pain, ambulatory or nonambulatory paraparesis, and decreased anal and tail tone. Cats will occasionally present with fractures/luxations of the sacrococcygeal region resulting from suspected traction injury. It is theorized that car tires trap the tails of these cats as the cats are running to avoid being hit. The resultant traction applied to the cauda equina may result in temporary or permanent neurologic damage. These cats often display varying degrees of urinary and fecal incontinence, in addition to tail dysfunction. Some cats also exhibit pelvic limb dysfunction.

Physical Examination Findings

Severe traumatic injury often produces additional injuries (e.g., cardiopulmonary, urinary, diaphragmatic hernia, appendicular skeleton, a second vertebral fracture/luxation). A thorough physical examination of each system to identify concurrent injury is necessary. Patients that struggle during physical examination or those with profound neurologic deficits should be secured to a rigid platform to prevent further nerve root trauma until a definitive course of action can be taken.

Lumbosacral fracture/luxation may cause trauma and sustained compression to the cauda equina. The most commonly involved

nerve roots are L6, L7, S1–S3, and Cd1–Cd5. Major nerves associated with these nerve roots include the sciatic nerve (L6, L7, S1, and/or S2), pelvic nerve (S1–S3), perineal and caudal rectal branches of the pudendal nerve (S1–S3), and caudal (coccygeal) nerves of the tail (Cd1–Cd5). Because of the regional anatomy innervated by the cauda equina, ischemia and/or compression may produce a wide variety of neurologic signs. Although a variety of neurologic deficits may occur, the most common presentation is lumbosacral hyperesthesia (pain on palpation of the lumbosacral junction), LMN ambulatory or nonambulatory paraparesis, varying degrees of anal sphincter hypotonia/atonia, and abnormalities in tail carriage and sensation.

Diagnostic Imaging

Neurologic examination localizes the lesion to the cauda equina. Survey radiographs are usually diagnostic and generally reveal an oblique or short oblique fracture through the vertebral body of L6 or L7, or a luxation or subluxation between L6 and L7 or L7 and S1. Although radiographs are a useful screening tool for trauma, we prefer CT imaging of lumbosacral trauma patients, as this modality is more sensitive than radiographs and allows for presurgical measurements for implant placement. MRI is also often used in lumbosacral trauma cases and has the advantage of delineating soft tissue structures more accurately than CT. The caudal fracture/luxation segment is characteristically displaced cranioventral to the cranial segment (see Fig. 42.12). Because of the relatively mild neurologic signs that may be seen with marked fracture or luxation displacement on survey radiographs, prognosis is based on neurologic examination findings, not radiologic findings. Moreover, as LMN signs predominate in patients with multiple spinal fractures, neurologic examination may not identify a second thoracolumbar fracture or luxation. A complete series of spinal radiographs or a whole body CT scan is always recommended in patients with spinal fracture or luxation.

NOTE Up to 20% of patients with spinal fracture or luxation have a second spinal fracture or luxation.

Laboratory Findings

Patients presenting with lumbosacral fracture/luxation secondary to severe trauma often have a stress leukogram and elevated hepatic enzymes. If patients sustain concurrent injuries resulting in uroabdomen, ruptured spleen, or pulmonary contusion, associated laboratory abnormalities may occur. Laboratory findings are usually nonspecific.

DIFFERENTIAL DIAGNOSIS

Fracture/luxation of the lumbosacral spine must be differentiated from other disorders causing cauda equina compression, including DLSS, discospondylitis, chronic degenerative disc disease, intervertebral disc extrusion, fibrocartilaginous embolism, and neoplasia of the spine, surrounding soft tissue, and nerve roots. Definitive diagnosis is made by analyzing history, neurologic localization, and imaging results.

MEDICAL MANAGEMENT

Objectives of medical management include immobilization of the spine and patient confinement until fracture/luxation stabilization and union occur. The following conditions are recommended: strict confinement for 4 to 6 weeks in a dry, elevated padded cage; analgesics/NSAIDs as needed to control back pain (do not use steroids and NSAIDs concurrently or in close temporal proximity to each other); urinary bladder expression or intermittent catheterization four times daily; passive physical therapy of the hind legs two to three times daily; and serial neurologic examinations twice daily to assess patient response to therapy.

SURGICAL TREATMENT

Objectives of surgical management are decompression of the cauda equina (fracture/luxation reduction) followed by adequate spinal stabilization. Infrequently, patients may require dorsal laminectomy for complete decompression (when bone fragments are present in the vertebral canal and/or intervertebral foramen) or for its prognostic value in evaluating the severity of cauda equina damage. The process of surgical reduction and stabilization provides immediate relief of back pain, allows freedom of movement, decreases patient morbidity, and protects spinal roots from further trauma. Surgical versus medical treatment is based on the patient's neurologic status at presentation, response to medical management, and serial neurologic examinations. There are numerous fixation methods for the lumbosacral region, some of which are described in this chapter. Adequate stabilization of the lumbosacral junction can be provided by a number of techniques, including (1) transilial pins with Kirschner clamps, bent pins, or bone cement; (2) transilial pins and plastic dorsal spinous process plates; (3) transilial pin, dorsal spinous process plates, and external skeletal fixation; (4) modified segmental spinal fixation; (5) vertebral body and/or pedicle Steinmann pins/screws embedded in polymethylmethacrylate (PMMA) bone cement; and (6) dorsal locking plates (string of pearls).[10,11] A pedicle screw-rod fixation method has been described for stabilizing the L7–S1 articulation in dogs with DLSS; this procedure could also be applied to trauma cases.[12] Transarticular cortical screw placement across the L7–S1 articular processes (facets) can also be used for stabilization but has been shown to have a fairly high incidence of implant failure in one study.[13] We recommend that these screws, if used, should not be the sole method of stabilization. Choice of technique is generally dictated by the surgeon's experience and equipment available.

Preoperative Management

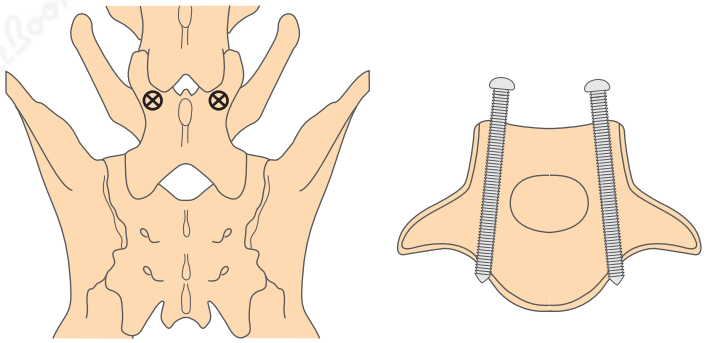
Preoperative management of patients with cauda equina compression is similar to that described for any lumbosacral compressive lesion (see p. 1428). If concurrent spinal cord injury is not present, preoperative steroids are not recommended because they do not protect nerve roots. Lumbosacral instability predisposes the patient to further trauma, and care should be taken to support the patient's pelvis during preoperative manipulations.

Anesthesia

Suggested anesthetic regimens for use in patients with spinal disorders are discussed on p. 1366.

Surgical Anatomy

Pertinent surgical anatomy of the lumbosacral area and cauda equina is discussed on pp. 1404 and 1428. For purposes of implant placement, the surgeon should also be familiar with implant entry points for pedicle pins/screws (Fig. 42.13).



A B

FIG. 42.13 (A) Approximate dorsal implantation site and (B) cross-sectional view of the appropriate angle of implant insertion for caudal lumbar pedicle pins/screws.

Positioning

The surgical approach for each stabilization technique requires dorsal exposure. Positioning the patient in sternal recumbency with the hind legs tucked under the abdomen encourages flexion of the dorsal lumbosacral region and facilitates fracture reduction and cauda equina decompression (see Fig. 42.3).

SURGICAL TECHNIQUES

Transilial Pins

This procedure is limited to L7–S1 luxations and L7 fractures in which the dorsal lamina is intact. *Expose dorsal spinous processes and lamina of L6, L7, and the entire median sacral crest as described for dorsal laminectomy on p. 1429.* Because of the cranioventral displacement of the sacrum, visualization of the cranial aspect of the sacral crest is obscured by the lamina of L7. L7 laminectomy is not compatible with this technique. *Use a periosteal elevator or small osteotome to elevate epaxial muscles and expose the articular processes of L7. Use the tip of a Kelly or Carmalt forceps or a Senn retractor and carefully place it in the lumbosacral junction. Visually monitor the depth of placement of the forceps or retractor to avoid injuring nerve roots. Hook the tip of the forceps or retractor under the cranial lamina of the sacrum to act as a lever against the caudal lamina of L7 (Fig. 42.14).* Depending on patient size, a Senn retractor can also be used under the cranial lamina of S1 to lever the sacrum back into alignment with L7. Reducing the fracture or luxation facilitates adequate exposure of the lumbosacral junction. *Before attempting reduction, place a bone forceps (e.g., speed-lock reduction forceps) or towel clamp in the wing of each ilium or in the spine of L6 or L7 to provide countertraction.* These manipulations force the sacrum caudodorsally, to reduce the fracture/luxation. *Visualize the lumbosacral articular processes (facets); when the articular processes of L7 and S1 are reapposed, reduction is anatomic. Place a 0.062-inch (1.575 mm) Kirschner wire through each L7–S1 articular facet to maintain fracture or luxation reduction. Next, incise gluteal fascia on the dorsolateral crest of the wings of each ilium, elevate the middle gluteal musculature, and expose the dorsolateral aspect of each ilial crest. Place an appropriately sized Steinmann pin through the lateral aspect of the ilial wing, across the dorsal lamina of L7, and through the opposite ilial wing. Place a second pin in a similar fashion starting from the opposite side (Fig. 42.15A). Be sure both pins cross over the dorsal lamina of L7. Prevent pin migration by employing one of the following techniques: (1) bend the ends of each pin at a 90-degree angle (Fig. 42.13A); (2) connect the pins on each side with double Kirschner clamps of the appropriate size (Fig. 42.15B); or (3) notch the pins' ends with a pin cutter and incorporate them with PMMA bone cement (Fig. 42.15C). If indicated, remove the interarcuate ligament and perform sacral laminectomy to visualize nerve roots. Lavage the surgical wound with sterile physiologic saline solution, cover the ends of the pins by closing gluteal fascia, and close epaxial muscles by apposing dorsal midline fascia. Close subcutaneous tissue and skin routinely.* This procedure can be combined with dorsal spinous process plating (Fig. 42.16) for additional stability or if L6 is also fractured or luxated.

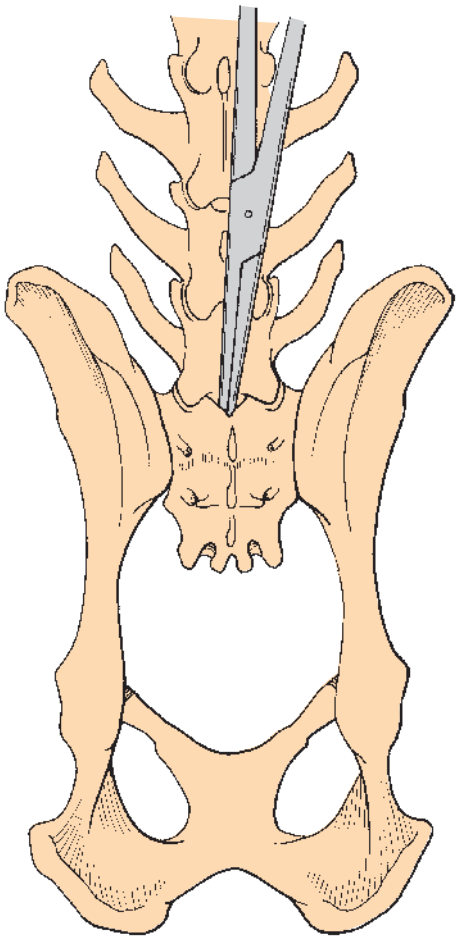


FIG. 42.14 Use of Kelly or Carmalt forceps to aid reduction of an L7 fracture. Hook the tip of the forceps under the cranial lamina of the sacrum and lower the jaws against the caudal lamina of L7.

Modified Segmental Spinal Fixation

Modified segmental spinal fixation can be used in patients of all sizes. It does not require deep exposure, and it is compatible with dorsal laminectomy, relatively straightforward to perform, versatile (it can be used in combination with other techniques), and results in a stable repair. Modified segmental spinal fixation is also described for thoracolumbar spinal injury on p. 1418. *Approach the dorsal aspect of the lumbar and lumbosacral spine as described earlier for transilial pins and dorsal spinous process plates. Expose three dorsal spinous processes cranial to the fracture or luxation.*

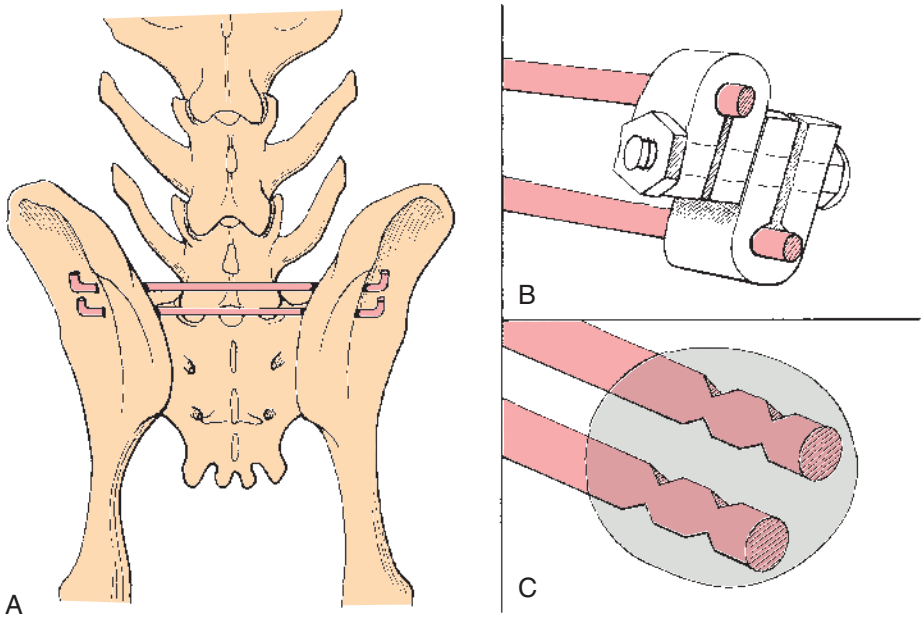

FIG. 42.15 Prevent migration of transilial pins by (A) bending the ends of each pin at a 90-degree angle, (B) connecting the pins on each side with a double Kirschner clamp, or (C) notching the pin ends with a pin cutter and incorporating them with bone cement.

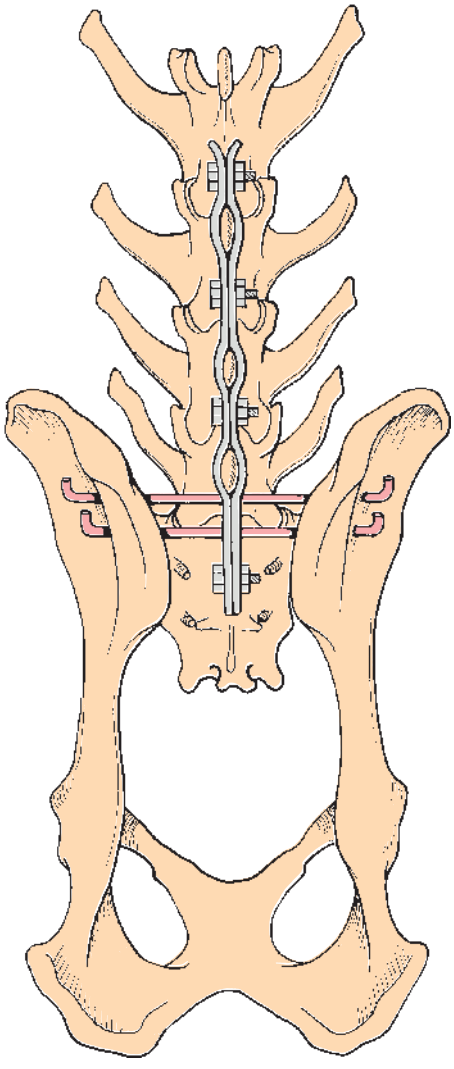

FIG. 42.16 Transilial pins and plastic dorsal spinous process plates to repair L7–S1 fractures or luxations.

Expose, carefully reduce, and maintain fracture or luxation reduction as described for transilial pinning on p. 1439. Perform a dorsal laminectomy at this time, if indicated (see p. 1429). Drill holes in the caudal articular processes and bases of dorsal spinous processes of at least two to three vertebrae cranial to the fracture or luxation. Drill holes in the cranial sacral articular facets to ensure a minimum of two points of fixation per pin in the sacroiliac segment. Preplace 3- to 4-inch (7–16 cm) lengths of 18- to 20-gauge stainless steel wire through each hole. Drill two holes transversely through each ilial wing at the level of the dorsal lamina of the sacrum. Bend four appropriate size and length Steinmann pins at a 90-degree angle, remove the points, and pass the pins through the holes drilled in the wings of the ilia. Place the pins alongside the lamina and attach them to the articular facets and dorsal spinous processes using the preplaced stainless steel wires (Fig. 42.17).

Steinmann Pins/Screws and Polymethylmethacrylate

Steinmann pins and/or screws and PMMA bone cement can be used in patients of all sizes. These constructs can also be modified by adding support rods (connecting the vertebral pins and/or screws) prior to PMMA placement (Fig. 42.18). This technique requires exposure of the dorsal surface of the transverse processes of L6 and L7 and is compatible with dorsal laminectomy, is versatile (it can be used in combination with other techniques), requires constant reference to an anatomic specimen (e.g., spine), and provides a stable repair. In the caudal lumbar vertebrae, pins/screws can be placed primarily in the vertebral bodies by directing the implants between the accessory process and transverse process (see p. 1423), or primarily in the vertebral pedicle, starting from a dorsal entry point just caudal to the cranial articular facet (roughly the middle of the facet) and directing the implant slightly laterally (see Fig. 42.13). This latter method of vertebral implant placement is often chosen for the caudal lumbar vertebrae (L6, L7) as the angle for more direct vertebral body implant placement can be difficult to achieve due to interference by the ilial wing. When placing implants primarily into the pedicle of caudal lumbar vertebrae, create a small entry point in the cortical bone with a small burr, prior to implant

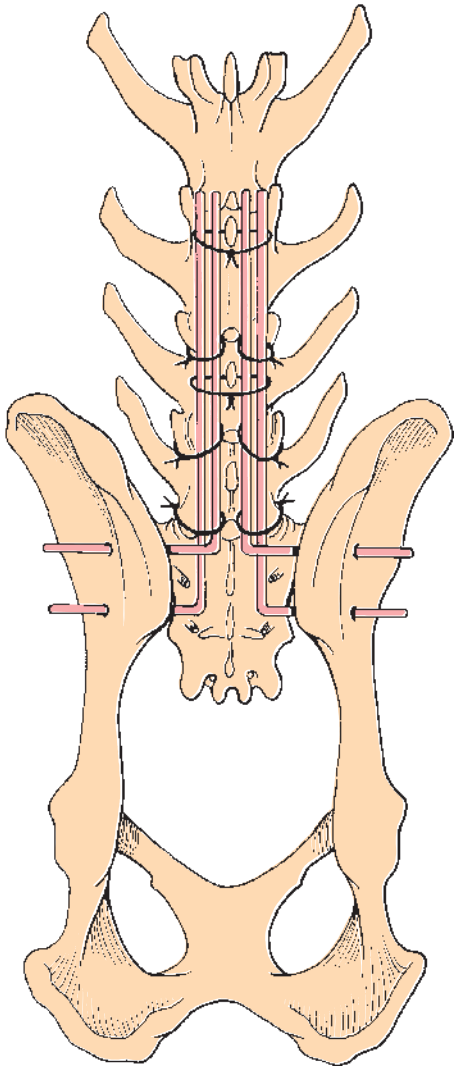

FIG. 42.17 Diagram showing proper pin placement for modified segmental spinal fixation of L6, L7, and S1 fractures or luxations.

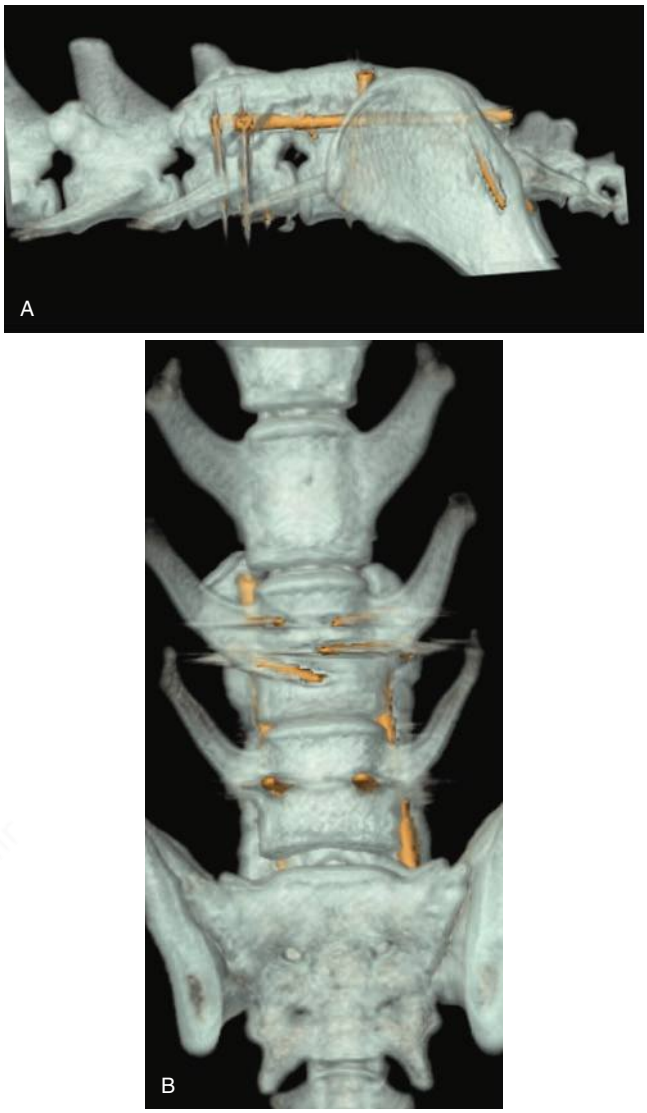

FIG. 42.18 (A) Lateral and (B) ventral views of postoperative three-dimensional computed tomography reconstructed images of a dog with a traumatic L6–L7 luxation repaired with screws, rods, and polymethylmethacrylate.

placement or predrilling (in case of screw placement). Otherwise, the implant or drill bit is likely to constantly slip off this curved area of bone. *Adequately expose the vertebrae cranial and caudal to the fracture or luxation. Incise muscle attachments to articular facets and periosteally elevate epaxial muscles until the dorsal aspect of the transverse processes of L6 and L7 and dorsal lamina of the sacrum are identified. Reduce the fracture/luxation and maintain reduction as described for transilial pinning on p. 1439. If the fracture involves the body of L6, place two pins/screws (one on each side) in the pedicle/body of L5 and two pins/screws in the pedicle/body of L7. If an L6–L7 luxation is being repaired, place two pins/screws in the pedicle/body of L6 and two pins/screws in the pedicle/body of L7. Place pins/screws and apply bone cement using the technique described on p. 1439. If the fracture involves the vertebral body of L7 or is an L7–S1 luxation, place two pins/screws in the pedicle/body of L6, two pins/screws in the pedicle/body of L7, and two pins/screws in the cranial articular process of S1 with penetration through the ilium. If the fracture involves the vertebral body of L7, pin/screw placement in L7 is dictated by the type of fracture present (e.g., avulsion fracture of the end-plate, place two pins/screws in L7; transverse fracture, place one or two smaller pins/screws, depending on the size of the fracture fragments; comminuted fracture, no pins should be placed in L7). Insert pins/screws directly into the pedicles/vertebral bodies of L6 or L7 using the accessory process and transverse process as landmarks. Insert pins/screws into the center of the cranial articular processes of S1. Drive the pin/screw until it penetrates the gluteal surface of the wing of the ilium. Direct the L6 and L7 pins/screws cranioventral and from lateral to medial, and the S1 pins/screws caudoventral and from lateral to medial. Drive pins/screws to exit 2 to 3 mm from the ventral aspect of the vertebral bodies and wings of the ilia. If pins are used (vs. screws), cut pins to leave 2 cm protruding and notch the exposed pinheads with a pin cutter. Thoroughly lavage and dry the surgical field (Fig. 42.19). Apply PMMA bone cement as described on p. 1439. If necessary, excise portions of epaxial muscles adjacent to the PMMA to facilitate closure. Close subcutaneous tissues and skin routinely.*

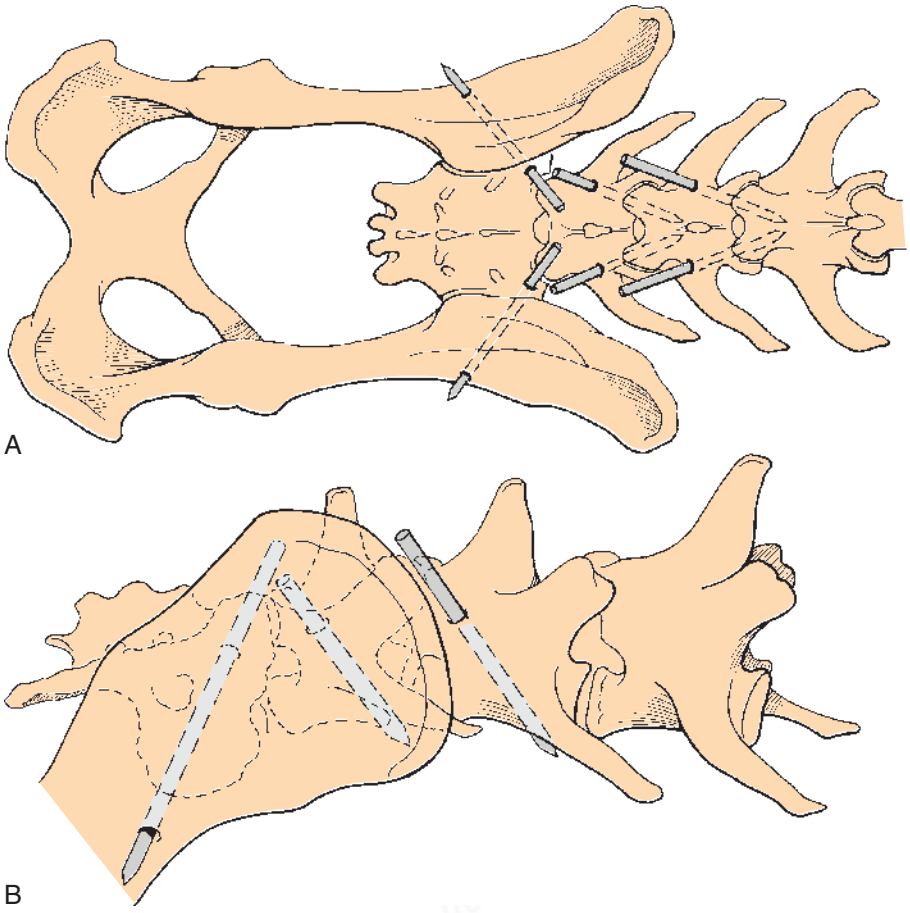

FIG. 42.19 (A) Dorsal and (B) lateral views showing proper pin placement in the iliac wings, articular facets of S1, and vertebral bodies of L6 and L7 when using Steinmann pins and polymethylmethacrylate to repair L6, L7, and S1 fractures or luxations.

SUTURE MATERIALS/SPECIAL INSTRUMENTS

Depending on the technique chosen, the following special instruments will be needed: plastic dorsal spinous process plates, bone cement, Steinmann pins, cortical screws, string-of-pearls plate set, skeleton, and Kirschner-Ehmer clamps and connecting bars.

POSTOPERATIVE CARE AND ASSESSMENT

Patients with lumbosacral fracture/luxation should be monitored postoperatively, as are patients with other lumbosacral disorders (i.e., strict confinement, analgesics as needed, short walks using an abdominal sling, frequent urinary bladder evacuation, and daily neurologic examinations). Long-term assessment consists of neurologic examinations and awake or sedated spinal radiographs at 1, 2, 3, 6, 9, and 12 months after surgery or when the fracture or luxation resolves.

PROGNOSIS

Prognosis depends on severity of cauda equina compression (i.e., on neurologic examination at presentation) and the treatment regimen chosen. Cauda equina nerve roots withstand considerably more trauma than the spinal cord. Patients with 100% lumbosacral vertebral canal compromise may retain neurologic function of the pelvic limbs, anus, urinary bladder, perineum, and tail; their prognosis is favorable. In general, the preservation of pain sensation (nociception) in the areas of innervation of the cauda equina nerve roots is a favorable prognostic indicator. However, patients with profound neurologic deficits (e.g., complete loss of motor function and deep pain perception in the sciatic nerve distribution, lack of anal tone and bladder tone with no perineal sensation) should be given a guarded prognosis, regardless of the percentage of vertebral canal compromise. As the severity of presenting neurologic deficits increases, early decompression and stabilization allow a more favorable prognosis. If neurologic deterioration during medical management is determined early, immediate surgical intervention produces a more favorable outcome. Cats with tail traction injuries often make full recoveries, especially if anal tone and perineal sensation are intact, and appropriate bladder management is instituted soon after injury. Failure to regain urinary continence within 1 month of trauma in these cats is a negative prognostic indicator. Lateralized sacral fractures in dogs tend to have a better prognosis for neurologic recovery than those located in a more central location.

NOTE The amount of vertebral canal compromise observed on lateral radiographs should not be used as a prognostic indicator.

Nonsurgical Disorders of the Brain and Spine

There are a number of nonsurgical disorders of the brain and spine that neurosurgeons need to be familiar with because (1) these disorders can mimic surgical disorders and are often presented as such for diagnosis and possible surgery, and (2) some of these disorders require imminent diagnosis and treatment for a positive outcome. If presented with such patients, it is incumbent on the neurosurgeon to either be comfortable in diagnosing and treating these animals or to quickly recognize the nature of the disease process and arrange for care with the appropriate specialist. In some cases, a biopsy will be required for diagnosis. Although currently done infrequently, the use of stereotactic brain biopsy equipment that interfaces with both magnetic resonance imaging (MRI) and computed tomography (CT) is increasingly being used in veterinary neurosurgery. The distinction between surgical and nonsurgical disease of the brain and spine is not always clear; discospondylitis is usually considered to be solely a medical disorder; however, some patients will develop compressive lesions (e.g., infected epidural fat) and/or vertebral instability, either of which may require surgical intervention.

SPECIFIC DISEASES

CANINE COGNITIVE DYSFUNCTION/COGNITIVE DYSFUNCTION SYNDROME

DEFINITIONS

Canine cognitive dysfunction (CCD) is the canine analog of human Alzheimer disease (AD). This disorder is also referred to as **cognitive dysfunction syndrome (CDS). Beta amyloid (Aβ)** is a neurotoxic protein that accumulates in the brains of dogs and cats with cognitive dysfunction, and humans with AD, that forms plaques within the brain parenchyma. Accumulation of Aβ also leads to cerebrovascular disease, referred to as **cerebrovascular angiopathy. Tau protein** is another protein that accumulates in the brain of aging pets and humans with cognitive dysfunction.

GENERAL CONSIDERATIONS AND CLINICALLY RELEVANT PATHOPHYSIOLOGY

CCD is an age-related disorder, similar to AD in people, that occurs in elderly dogs; an analogous disorder also occurs in cats. Age-related cognitive dysfunction is best described for the dog, and this species appears to be the best animal model available for human AD. Similar to AD in people, the pathophysiology of CCD is uncertain. There are pathologic similarities between the brains of humans with AD and dogs and cats with age-related cognitive impairment. Cerebral vascular changes, meningeal thickening, gliosis, and ventricular dilatation occur in brains of both AD and CCD patients. More specifically, progressive accumulation of a neurotoxic protein called Aβ in the brain (in and around neurons) is a consistent feature in both AD and CCD. These accumulations coalesce to form plaques (neuritic plaques) and are most prominent in the frontal cerebral cortex and hippocampus in both human and veterinary disorders. The most common form of insoluble Aβ found in brain tissue is a 42 amino acid form, called $A\beta_{42}$. In addition to this insoluble form of the protein, smaller soluble oligomeric forms of Aβ have been identified; these are highly toxic and interfere with synaptic function.[1] In both human and veterinary disorders, the degree of Aβ accumulation has been correlated with the extent of cognitive impairment. In one histopathologic study of CCD dogs, however, cognitive impairment was associated with increased numbers of astrocytes and microglial cells, as well as elevated ubiquitin protein levels, rather than with levels of Aβ.[2] In addition to the accumulation of neurotoxic Aβ (protein in the aged canine and feline brain), intraneuronal accumulation of a hyperphosphorylated microtubular-associated protein (tau protein) has also been demonstrated. Tau protein is the precursor to neurofibrillary tangles (NFTs), another prominent histopathologic feature of human AD. The absence of mature NFTs in the brains of dogs and cats with age-related cognitive dysfunction has been argued as evidence against the canine and feline disorders as being analogous to human AD. However, the absence of NFTs in dogs and cats has a number of potential explanations. It is possible that dogs and cats do not live long enough for the tau proteins to develop into NFTs as they do in people. Although the amino acid sequence of Aβ protein is identical in humans and dogs, this is not the case for tau protein. The amino acid sequence of dogs and cats differs from that in people; this different sequence may affect the ability of tau protein to form NFTs. Other structural abnormalities found in the aging canine brain that are similar to those in humans include cerebral atrophy, ventricular enlargement, blood vessel wall fibrosis, amyloid deposition (meningeal and parenchymal), microhemorrhages and infarcts, axonal degeneration with myelin loss, astroglial hypertrophy and hyperplasia, and intraneuronal accumulation of several substances (lipofuscin, polyglucosan bodies, and ubiquitin).

The pathophysiology of CCD and AD is multifactorial and complex. There is evidence in both diseases that increased oxygen–free radical mediated cellular damage, decreased endogenous antioxidant defenses, inflammation (from various processes),

ABSTRACT

Numerous nonsurgical conditions are likely to be regularly encountered by surgeons who perform brain and spinal surgery (e.g., cognitive dysfunction, ischemic brain and spinal cord problems, inflammatory brain disease, degenerative myelopathy, steroid-responsive meningitis-arteritis, and discospondylitis). Whether or not the attending surgeon will remain the primary clinician, it is important to have at least a working knowledge of the diagnostic and therapeutic options available. In some instances (e.g., inflammatory disorders), the surgical clinician may need to initiate treatment prior to seeking advice from another specialist if the patient is going to have a positive outcome.

decreased mitochondrial function, DNA damage, vascular compromise, and neurotransmitter imbalance are all interrelated processes that are involved in progressive cognitive impairment. Neurochemical changes that occur in the aging brain are thought to contribute to progressive cognitive impairment. An age-associated decline in the brain neurotransmitter levels of acetylcholine, dopamine, norepinephrine, and *gamma-aminobutyric acid* (GABA) has been documented in CCD and AD. Of these abnormalities, cholinergic dysfunction appears to have the highest and most consistent correlation with age-related cognitive impairment. Other neurochemical abnormalities identified in brains of CCD and AD patients include increased acetylcholinesterase levels (associated with cholinergic decline), increased monoamine oxidase B (catalyzes the breakdown of dopamine, with subsequent formation of free radicals), and elevated cerebrospinal fluid (CSF) levels of lactate, pyruvate, and potassium.

DIAGNOSIS

Clinical Presentation

Signalment

CCD occurs primarily in older dogs, usually greater than 9 years of age. Cats are less commonly affected by CDS and are typically older than 12 years of age at presentation. There is no apparent breed or sex predilection for CDS.

History

Historical complaints regarding CDS are numerous and often nonspecific. They include inattentiveness, inactivity, aimless wandering (often pacing at night), demented behavior, disturbance of the sleep/wake cycle, urinary and/or fecal incontinence, difficulty navigating stairs, becoming lost in previously familiar environments, failure to recognize previously familiar people or animals, decreased interaction with family members, hearing loss, excessive vocalization (often at night), and anxiety. Cats with CDS occasionally exhibit overresponsive and aggressive behavioral patterns. Owners of CDS pets often describe their pets as acting "senile." In one study of dogs with CCD, four key clinical features were identified: (1) anxiety, (2) disturbance of the sleep/wake cycle (sleeping during the day, restless at night), (3) decreased interaction with owners, and (4) apparent confusion or disorientation.[3]

Physical Examination Findings

Dogs and cats with CDS typically display evidence of forebrain dysfunction. These patients have abnormal mentation and often respond inappropriately to their environment (dementia). Many dogs and cats with CDS will circle constantly in the examination room and either not respond or respond inappropriately to visual and auditory stimuli. In addition to the classic behavioral abnormalities indicative of CCD in dogs, suspected CCD dogs will occasionally have either transient central vestibular dysfunction or seizure activity of recent onset. Although not well-described as a clinical feature of CCD, vestibulocerebellar dysfunction and seizures are reported as a potential consequence of AD in people.

Diagnostic Imaging

The only imaging modality of use for the diagnosis of CCD is MRI. Brain imaging of AD patients can be normal or may reveal brain atrophy, ventricular enlargement, and lesions in the medial temporal lobes of the cerebral cortex (Fig. 43.1). Age-related changes appreciated on MRI of the brain in CCD patients are primarily reflective of brain atrophy and include ventricular enlargement, widened and well-demarcated cerebral sulci, and diffuse and scattered areas of T2-hyperintensity in periventricular white matter. Although these are consistent findings associated with the aging brain, they may be found in older patients without evidence of CCD. The thickness of the interthalamic adhesion as measured on transaxial T1- and T2-weighted magnetic resonance (MR) images was found to be significantly smaller in dogs with CCD compared with dogs without CCD (Fig. 43.2); an interthalamic adhesion thickness of 5 mm or less was found to be consistent with a diagnosis of CCD.[4]

Laboratory Findings

Laboratory findings are typically normal in dogs and cats with CDS, unless there is an age-related concurrent disorder (e.g., elevated blood urea nitrogen/creatinine from chronic renal disease). It is important to measure fasting/postprandial serum bile acids and/or blood ammonia to distinguish CCD from hepatic encephalopathy. Dogs with CCD should have normal serum bile acids and blood ammonia. Congenital portosystemic shunts are sometimes not diagnosed until the dog is older than 10 years old, and mild hepatic encephalopathy may mimic findings expected in CCD.[5] In one study, plasma concentrations of $A\beta_{42}$ were significantly increased in dogs with CCD, compared with older dogs with either mild cognitive impairment or no cognitive impairment.[6]

DIFFERENTIAL DIAGNOSIS

The main differential diagnoses for CDS are brain tumor and metabolic encephalopathy (e.g., hepatic encephalopathy).

MEDICAL MANAGEMENT

There are numerous proposed therapeutic approaches to CCD, with variable evidence of efficacy in improving cognitive function and/or delaying progression of cognitive decline. The use of oral

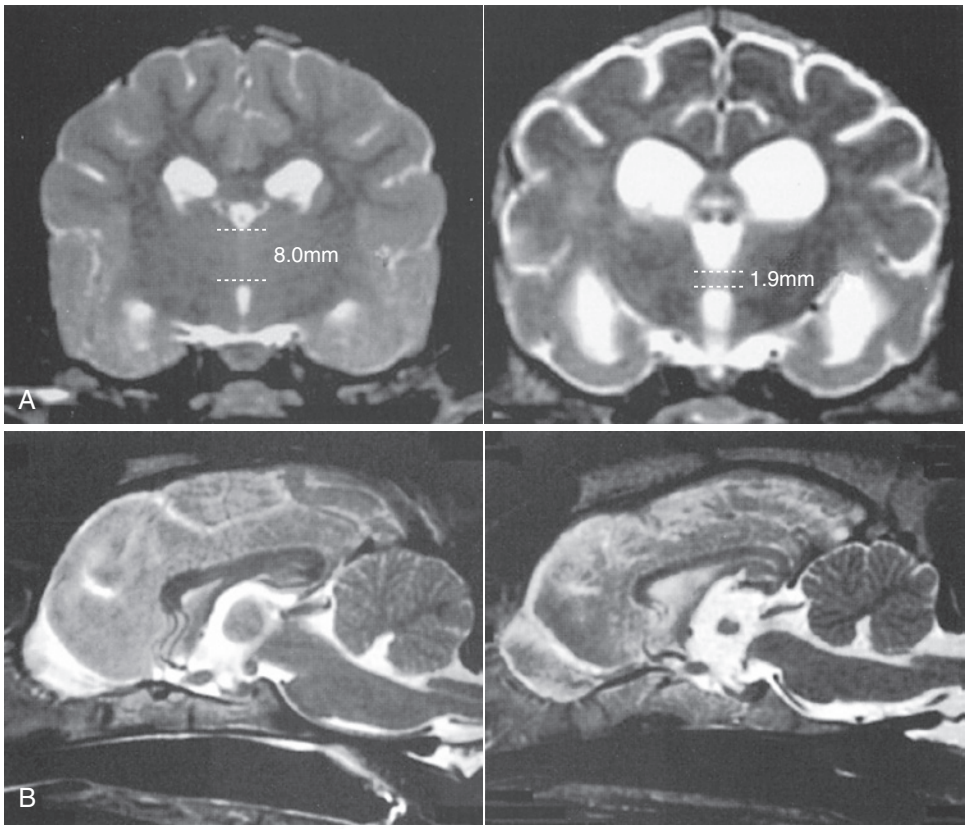

FIG. 43.2 (A) Axial and (B) midsagittal T2-weighted magnetic resonance images, demonstrating normal *(left)* and abnormal (*right;* cognitive dysfunction syndrome patient) interthalamic adhesion thicknesses in dogs. (Courtesy Dr. D. Hasegawa.)

L-deprenyl (selegiline; Anipryl, Atapryl, Carbex, Eldepryl, Zelapar), an irreversible inhibitor of monoamine oxidase B, has been purported to improve cognitive function and slow progression of the disease in the majority of dogs and cats with CDS. There is considerable variability in the degree of response achieved among patients, however. L-deprenyl is thought to exert its beneficial effects in the brain by restoring dopaminergic balance, as well as enhancing catecholamine levels and decreasing levels of damaging free radical species. The dosage for dogs is 0.5 to 1 mg/kg every 24 hours. Cats are administered 0.5 mg/kg every 24 hours. Most patients will exhibit a positive response within the first month of therapy. Despite apparent positive responses of both canine and feline CDS patients to selegiline, there is evidence that this drug does not have a significant effect on cognitive function in these patients or in people with AD. The clinical efficacy studies supporting selegiline use in CDS are based primarily on owner response to questionnaires rather than on standardized comparative cognitive testing procedures of treated and untreated patients. Because selegiline may produce nonspecific low-level hyperactivity by increasing brain catecholamine levels, the "response" observed by owners may not truly be representative of improved cognitive ability. Selegiline is not considered an effective drug for human AD because of variable responses and overall minimum improvement of cognitive function. The acetylcholinesterase inhibitor phenserine has exhibited efficacy in improving cognitive function in both dogs with CCD and humans with AD in clinical trials; to our knowledge, this drug is not yet commercially available for dogs. Behavioral changes in CCD patients may be alleviated with the use of GABA-ergic drugs, such as gabapentin or pregabalin. Because inflammatory changes have been identified in the brains of CCD dogs, the use of antiinflammatory drugs (e.g., carprofen) has also been proposed. Some naturally occurring phytochemicals (e.g., curcumin, resveratrol, green tea catechins) may hold some promise as treatment options for CCD. Oral S-adenosylmethionine has been shown to be effective in improving clinical signs of mental decline in CCD dogs in one study.[7] A large number of complementary therapies have been suggested for the treatment of CCD, with the primary goals of calming the patient, reducing anxiety, and normalizing the sleep-wake cycle. These include melatonin, valerian root, dog-appeasing pheromone, phosphatidylserine, ginkgo biloba, DHA (an omega-3 fatty acid), and various antioxidants and mitochondrial cofactors. The evidence for efficacy of these complimentary therapies is entirely anecdotal. There is convincing evidence that providing a diet fortified with antioxidants, mitochondrial cofactors, and essential fatty acids improves cognitive function and delays cognitive decline in dogs with CCD. This commercially available diet (Hills b/d) contains a mixture of fruits and vegetables, in addition to vitamins C and E, and mitochondrial cofactors (L-carnitine, DL-α-lipoic acid). Environmental enrichment, such as regular exercise and introduction of new toys, has also been demonstrated to improve cognitive function and delay cognitive decline in dogs with CDS. Progression of CDS appears to be more rapid in castrated versus intact male dogs, suggesting a potential role for hormone replacement therapy in this disease. Recent evidence suggests that the anticonvulsant drug levetiracetam (see Chapter 39) is effective in improving cognitive function and decreasing hyperexcitability in AD and animal models of AD; potential mechanisms of action include improved central nervous system (CNS) mitochondrial function

(and associated improved synaptic transmission) and inhibition of oligomeric Aβ-induced astrocyte glutamate release.[8–10]

SURGICAL TREATMENT

There is no surgical treatment for CDS.

PROGNOSIS

The prognosis for CCD has long been considered guarded due to its progressive nature and lack of effective treatment options. However, two long-term CCD studies showed no effect of the diagnosis of CCD on survival, compared with older dogs without CCD.[3,6] This suggests that CCD, despite being a progressive neurologic disorder, can often be successfully managed medically.

DEGENERATIVE MYELOPATHY

DEFINITIONS

Degenerative myelopathy (DM) is an inherited degenerative disorder of the spinal cord, primarily affecting the thoracolumbar region (T3-L3 segments).

GENERAL CONSIDERATIONS AND CLINICALLY RELEVANT PATHOPHYSIOLOGY

DM is a heritable, progressive degeneration of axons and myelin in all funiculi of the spinal cord, primarily in the thoracolumbar region. It is currently thought that DM is the canine analog of a form of human amyotrophic lateral sclerosis. A genetic mutation in the superoxide dismutase 1 *(SOD1)* gene has been identified in dogs with DM; this mutation leads to intraneuronal accumulation of cytotoxic cytoplasmic aggregates that stain with anti-SOD1 antibodies. Loss of axons with secondary demyelination has been demonstrated in both the CNS and peripheral nervous system of affected dogs. Dogs that are homozygous for the gene mutation are at risk for developing DM. As not all dogs homozygous for the SOD1 mutation develop clinical signs of DM and heterozygotes do not develop clinical features of the disorder, the mutation is suspected to be a recessive trait with incomplete penetrance.[11–13]

DIAGNOSIS

Clinical Presentation

Signalment

This is a disorder that primarily affects older (≥8 years), large-breed dogs. German shepherds are by far the most commonly affected, but other dog breeds and one cat have been reported to be affected. Additionally, a form of DM has been described in Pembroke Welsh corgis. There appears to be a female predominance for the disease in corgis. A list of dog breeds believed to be predisposed to DM is provided in Box 43.1.

History

The typical history is that of progressive (months), nonpainful pelvic limb weakness and ataxia. Clinical signs of dysfunction often start with dragging or scuffing the toes of the pelvic limbs, followed by ataxia and paraparesis. Dogs often have difficulty jumping.

BOX 43.1 Dog Breeds Thought To Be Predisposed to Degenerative Myelopathy

German shepherd
Boxer
Corgi (Pembroke and Welsh Cardigan)
Standard poodle
Rhodesian ridgeback
Collie
Irish setter
Bernese mountain dog
Chesapeake Bay retriever
Kerry blue terrier
Wire-haired fox terrier
Mixed-breed

Physical Examination Findings

Loss of pelvic limb proprioceptive ability (ataxia, toe dragging) is noticed initially, followed by gradual loss of voluntary motor function. Spinal reflexes in the pelvic limbs are typically normal to hyperreflexive. Decreased to absent patellar reflexes are found in approximately 10% to 15% of patients, however, and may reflect selective damage to dorsal lumbar nerve roots in these dogs. Pelvic limb tremors may be present during weight support. Late in the disease process, urinary and/or fecal incontinence may develop. Dogs often develop disuse atrophy of the pelvic limb musculature over time (see the discussion under Prognosis).

Diagnostic Imaging

Spinal imaging (myelogram, MRI, CT) is typically normal, but some dogs may have concurrent mild type II disc lesions that are probably clinically insignificant. In one study of CT/myelography performed in dogs with DM,[14] a number of abnormalities were identified when compared with normal dogs, including vertebral canal stenosis, deformed spinal cord, small spinal cord, focal attenuation of the subarachnoid space, and paraspinal muscle atrophy. A definitive diagnosis of DM is based on characteristic histopathologic lesions in the spinal cord at necropsy.

Laboratory Findings

Bloodwork (complete blood cell count [CBC], serum biochemistry) is generally normal. CSF results are typically normal or have increased protein concentration with a normal cell count. There is a genetic test available for DM to identify those dogs with the SOD1 mutation.

DIFFERENTIAL DIAGNOSIS

Major differential diagnoses for DM are chronic type II disc protrusion and spinal neoplasia.

MEDICAL MANAGEMENT

No proved effective therapies are available for DM. Treatment is supportive care. Intensive daily physiotherapy may improve survival time in DM dogs.

SURGICAL TREATMENT

There is no surgical treatment for DM.

PROGNOSIS

The disease usually progresses over a 9- to 18-month period, eventually reaching a point at which the patient is nonambulatory in the pelvic limbs. The disease can progress to involve the thoracic limbs and eventually the brain stem in dogs kept alive after this degree of deterioration. This happens infrequently because most patients are euthanized once they reach the stage of nonambulatory paraparesis or paraplegia.

ISCHEMIC/VASCULAR DISEASE

DEFINITIONS

Infarct and **stroke** are synonymous terms used to denote a focal interruption of blood supply to a region of the CNS. In the brain, infarcts are often referred to as **lacunar** (small, from interruption of small vessel tributaries) or **territorial** (large, from interruption of a major vessel). They are also described as **hemorrhagic** or **nonhemorrhagic**, depending on whether or not there is an associated bleed around the region of vascular disruption. In the spinal cord, most infarcts are due to a disorder called **fibrocartilaginous embolic myelopathy (FCE),** where the material causing the infarct has been shown to be identical to nucleus pulposus fibrocartilage.

GENERAL CONSIDERATIONS AND CLINICALLY RELEVANT PATHOPHYSIOLOGY

There are multiple potential causes for brain infarcts, including systemic hypertension (primary/essential hypertension or secondary to underlying disease such as chronic renal failure, hyperadrenocorticism, or pheochromocytoma), cardiac disease, hypercoagulability, increased blood viscosity (e.g., polycythemia vera, multiple myeloma), intravascular neoplasia (e.g., lymphoma, hemangiosarcoma), infectious disease, and atherosclerosis (e.g., associated with hypothyroidism, diabetes mellitus, or hyperlipidemia). In people with strokes, an underlying cause is not identified in approximately 40% of cases; these infarcts are termed "cryptogenic." The percentage of cryptogenic strokes in dogs is believed to be similar to that in people. In contrast to humans, atherosclerosis appears to be rarely associated with canine brain infarcts; when it does occur in dogs, it is most likely to be associated with hypothyroidism. Brain infarcts in dogs are typically nonhemorrhagic and are most common in the cerebellum, cerebrum, and thalamic/midbrain regions. Multifocal brain infarcts have been reported but are comparatively uncommon. Cerebellar and cerebral infarcts tend to be territorial, involving the territories of large arteries, such as the rostral cerebellar artery and middle cerebral artery, respectively. These territorial infarcts tend to primarily involve the gray matter with variable levels of white matter involvement. Thalamic/midbrain infarcts tend to be smaller lacunar lesions involving the smaller perforating arteries of this brain region. In one report, over half of the dogs with brain infarcts had an underlying metabolic disorder that could potentially lead to thromboembolic disease, the most common being chronic renal disease and hyperadrenocorticism.[15] Systemic hypertension was documented in nearly 30% of those dogs whose blood pressure was documented. In another study of cerebellar infarcts in dogs, systemic hypertension was identified in over 40% of those patients in which blood pressure was measured.[16] In our experience there is usually an underlying disease present that could potentially explain the presence of hypertension in these dogs, with chronic renal disease and hyperadrenocorticism being the most common disorders.

FCE is a common syndrome caused by the embolization of arterial and/or venous supply to an area of the spinal cord. The embolizing material has been identified as fibrocartilage and is believed to originate from the nucleus pulposus of the intervertebral disc. The mechanism or mechanisms by which this material reaches the spinal cord vasculature from the disc are unknown. Theories center either around venous entry of disc material (e.g., extrusion either directly into a venous sinus or venous system of vertebral bone marrow—a Schmorl's node) with retrograde movement into the spinal arterial system (Fig. 43.3) or direct entry to the spinal cord arterial system (e.g., into normal surrounding vasculature or neovascularization over the annulus fibrosus associated with concomitant type II disc degeneration).

DIAGNOSIS

Clinical Presentation

Signalment

Dogs are much more likely to present with ischemic/vascular events to the brain and spinal cord than cats. There is a wide age distribution for both brain infarcts and FCE. Most dogs

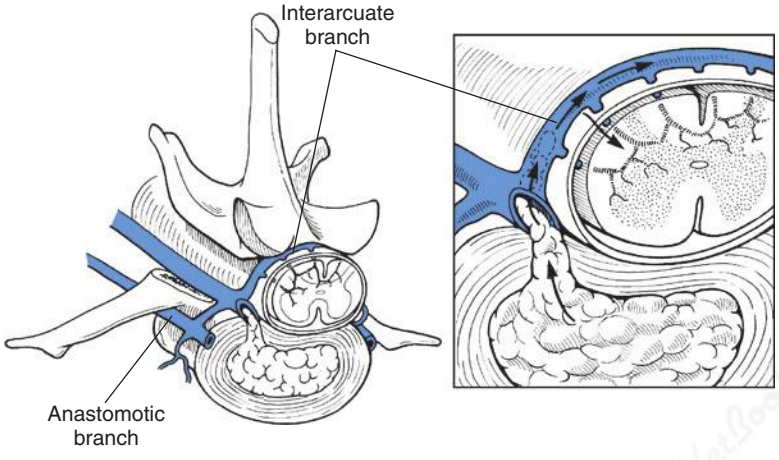

FIG. 43.3 Schematic illustration showing a proposed pathogenesis of a fibrocartilaginous embolism involving extrusion of nuclear material into the vertebral venous sinus or ventral spinal artery and then into small vessels supplying the spinal cord parenchyma.

presented with brain infarcts are middle-aged to older with median and mean ages of 8 and 9 years, respectively. Cerebellar infarcts appear to be most common in small-breed dogs, most notably the Cavalier King Charles spaniel. It has been postulated that this predisposition may be related to this breed's propensity to develop heart disease, inherited platelet abnormalities, or to local aberrations in regional arterial (e.g., basilar artery) blood flow resulting from Chiari-like malformations (CLMs), which is common in the breed. In people with atlantoaxial instability, basilar artery compression has been associated with cerebellar infarction. In our experience, the combination of CLMs and cerebellar infarct is common in the Cavalier King Charles spaniel, whereas combinations involving cardiac disease and platelet abnormalities are not. Large-breed dogs appear to be predisposed to developing lacunar thalamic/midbrain infarcts. Greyhounds may be predisposed to brain infarcts; one proposed reason is the tendency for greyhounds to have higher resting mean arterial blood pressures than other breeds. FCE typically affects non-chondrodystrophic dogs, mainly of large and giant breeds, but smaller nonchondrodystrophic dogs (e.g., Shetland sheepdogs, miniature schnauzers) and a number of cats have been reported. FCE has also been described in a few chondrodystrophic small-breed dogs. Approximately 20% of FCE patients are dogs less than 20 kg. Miniature schnauzers are predisposed to FCE, which is the most common cause of myelopathy in this breed. Most dogs presenting with FCE are young to middle-aged (1–7 years of age) adults. In one large (n = 393 dogs) retrospective report of canine FCE cases, FCE was most common in middle-aged, large-breed dogs (30% of the total), the most common single breed reported was the miniature schnauzer, and small-breed dogs accounted for 24% of the cases.[17] Most of the reported cats with suspected FCE have been middle-aged to older at presentation (7–12 years of age), and the majority were domestic shorthaired cats. Older cats (14–15 years) have also been reported with cranial cervical spinal cord infarcts involving the ventral gray matter at the C1–C2 vertebral level. These infarcts occur in the territory of the ventral spinal artery. A large proportion of these cats had concurrent disorders that could potentially be the cause of the infarct (e.g., chronic renal failure, cardiomyopathy).[18,19] In one retrospective report of 19 cats with ischemic myelopathy, there was a preponderance of domestic shorthaired cats, a male predominance, and an average age at presentation of 10 years; these findings were similar to previous reports of feline spinal cord infarcts.[20] Based on the available literature and our experience, FCE in cats occurs over a wide age range (including juveniles) and in multiple locations along the spinal cord. Spinal cord infarcts in the ventral gray matter of the cranial cervical cord tend to occur in very old cats and are associated with an underlying disease condition that may be responsible for hypertension and/or hypercoagulability (e.g., chronic renal failure, cardiomyopathy).

History

For both brain infarcts and FCE, clinical signs of neurologic dysfunction are typically peracute or acute onset and nonprogressive after the initial 24 hours of onset. In rare cases of FCE the time course of neurologic deterioration progresses over several days. Specific owner complaints depend on the location of the ischemic event in the CNS. In many cases of FCE, the patient is observed by the owner to be doing something active (e.g., chasing a ball in the yard) at the time of the ischemic event. At the time of the event, if observed, it is also common for the dog to cry out as if in pain. Shortly following the vascular event, dogs with FCE typically do not appear to be in pain.

Physical Examination Findings

The neurologic findings for both brain infarct and FCE patients reflect the location of the lesion within the brain and spinal cord, respectively. Paradoxical vestibular syndrome appears to be a common phenomenon with cerebellar infarcts. Although most MR images of territorial cerebellar infarcts in dogs suggest pure cerebellar involvement of the infarct, many of these patients have signs of medullary dysfunction (e.g., paresis or nonambulatory status) as well. This apparent discrepancy is believed to be explained by secondary medullary compression from the edema around the infarct at the time of the ischemic event. By the time the patient is imaged, this swelling is typically not apparent on the MRI. In one recent retrospective report of 23 dogs with suspected cerebellar infarcts, neurologic deficits included head tilt (13), ataxia with (11) or without (4) hypermetria, nystagmus (8), decreased menace response (7), postural reaction deficits (7), and nonambulatory status (6).[21] Another unusual clinical presentation common in dogs with thalamic/midbrain infarcts is the presence of central vestibular dysfunction. Dogs with infarcts in this area of the brain have had clinical signs such as ipsilateral head tilt (often in addition to a head turn, which would be expected with a forebrain lesion), strabismus, and nystagmus. Seizure activity has been reported in dogs with cerebral infarcts, but it does not appear to be very common. Clinical signs of myelopathy in FCE patients vary, depending on both the location and severity of the spinal cord ischemic injury. Deficits are often asymmetric with FCE. In the large retrospective study of 393 FCE dogs mentioned earlier, the most common neuroanatomic localization was T3–L3 (33.1%), followed by L4–S3 (31.8%), C6–T2 (20.6%), C1–C5 (10.7%), and multifocal (3.8%); clinical signs of myelopathy were asymmetric in 69.5% of cases.[17] These patients are typically not in pain on presentation. However, a focal region of hyperesthesia that corresponds to the infarct location can often be found if these patients are examined within 12 hours of the onset of clinical signs. This mild hyperesthesia is probably due to transient meningeal swelling in the infarct region.

Diagnostic Imaging

Brain and spinal cord infarcts are unlikely to be visualized on any other modality than MRI. CT may be more sensitive in detecting acute hemorrhage in early hemorrhagic stroke, but it offers no other advantages over MRI. Most brain infarcts in dogs and cats are nonhemorrhagic. MRI allows for greater detail in imaging (including detailed multiplanar images) and fewer artifacts (like beam-hardening artifact with caudal fossa images) compared with CT. Some functional MRI techniques (diffusion weighting, perfusion imaging, and MR angiography) can be used to improve the accuracy of stroke diagnosis, especially in the peracute stage of infarction (and especially within the first few hours). Table 43.1 summarizes the characteristic MRI appearance of nonhemorrhagic brain infarcts in dogs over time from infarction, using standard MRI sequences. Overall, nonhemorrhagic brain infarcts tend to be hyperintense on T2-weighted and fluid attenuation inversion recovery (FLAIR) images (see Chapter 14), hypointense on T1-weighted images, and minimally to non–contrast enhancing (Fig. 43.4). Contrast enhancement, usually at the periphery of the infarcted region, is typically evident 1 to 8 weeks following the ischemic event, presumably associated

TABLE 43.1 Characteristic MRI Appearance of Nonhemorrhagic Brain Infarcts Over Time

Stage	Time to Imaging	T2-Weighted MRI Findings	T1-Weighted MRI Findings	FLAIR Findings	Contrast Enhancement
Peracute	3–6 h	Hyperintense	Hypointense	Hyperintense	No
Acute	6–24 h	Hyperintense	Hypointense	Hyperintense	No
Early subacute	24 h–1 wk	Hyperintense	Hypointense	Hyperintense	Variable
Late subacute	1–6 wk	Hyperintense	Hypointense	Hyperintense	Yes
Chronic	>6 wk	Hyperintense	Hypointense	Hyperintense	Variable

MRI, Magnetic resonance imaging.

TABLE 43.2 MRI and CT Findings Associated With Different Stages of Hemorrhagic Brain Infarcts

Stage	Time to Imaging	T2-Weighted MRI Findings	T1-Weighted MRI Findings	CT Findings
Peracute	3–6 h	Slightly hyperintense	Isointense	Hyperdense
Acute	6–24 h	Hypointense	Isointense	Hyperdense
Early subacute	24 h–1 wk	Hypointense	Hyperintense	Hyperdense
Late subacute	1–6 wk	Hyperintense	Hyperintense	Variable
Chronic	>6 wk	Hypointense	Hypointense	Isodense

CT, Computed tomography; *MRI,* magnetic resonance imaging.

with disruption of the blood-brain barrier. The appearance of hemorrhagic infarcts on CT and MR images also varies with the time from the ischemic event and is dependent on the oxygenation state of hemoglobin. The "aging" stages of hemoglobin molecules progress sequentially as follows: oxyhemoglobin (peracute stage), deoxyhemoglobin (acute stage), methemoglobin (subacute stage), and finally hemosiderin and ferritin (chronic stage). Within the first several hours of a hemorrhagic infarct, the lesion is relatively isointense on T1- and T2-weighted MR images, but may show some hyperintensity on T2-weighted images due to edema surrounding the infarct. Deoxyhemoglobin subsequently forms over the next 24 hours, which is associated with low signal intensity on T1- and T2-weighted images. Intracellular methemoglobin predominates next, which is hyperintense on T1-weighted but hypointense on T2-weighted images. Subsequent accumulation of extracellular methemoglobin leads to a hyperintense signal on both T1- and T2-weighted images. Finally, hemosiderin and ferritin accumulate, which are low-signal intensity on both T1- and T2-weighted images. T2*-weighted (gradient recalled echo) sequences are very sensitive for identifying hemorrhagic lesions and should be routinely used in cases of suspected infarct.[22]

Both MRI and CT findings associated with different stages of hemorrhagic infarcts are summarized in Table 43.2. Hemorrhagic infarcts are also more likely to exhibit contrast enhancement compared with nonhemorrhagic infarcts (Fig. 43.5). The absence of an obvious spinal cord compressive lesion or mild focal thinning of the contrast column on myelography was the traditional method of tentatively diagnosing FCE. As with brain infarcts, MRI is also the preferred imaging modality for suspected FCE patients (Fig. 43.6); focal, sharply demarcated, hyperintense parenchymal lesions (suspected to be edematous, infarcted tissue) on T2-weighted and FLAIR images are characteristic. These lesions are isointense or hypointense to spinal cord on T1-weighted images and may display varying degrees of contrast enhancement (usually mild enhancement when present); the presence or absence of contrast enhancement may be related to the timing of MRI after the infarct occurs, often occurring approximately a week after injury in humans with FCE. The FCE lesions are often primarily within the gray matter of the spinal cord and unilateral in location. In one study of 52 dogs with suspected FCE, 11 dogs (21%) did not have any lesions apparent on MRI.[23] The appearance of lesions on MRI in this study was not associated with timing of imaging after infarction (in people, ischemic lesions may not be apparent on MRI within the first 48 hours of the infarct), but it was significantly associated with severity of neurologic dysfunction; ambulatory dogs were much more likely to have normal MRI results than nonambulatory dogs. This study also found a positive association between disease severity and lesion extent on MRI. In another large retrospective study for which 139 FCE dogs were imaged via MRI, 90.6% of dogs had T2 hyperintensity in the spinal cord parenchyma, 46% had subjective focal spinal cord swelling, and 22% had some level of contrast enhancement within or adjacent to the suspected infarct; 18% of cases had evidence of hemorrhage on T2* sequences.[17]

Laboratory Findings

Laboratory findings for patients with brain infarcts are variable, depending on whether or not there is an underlying disorder that may have led to the stroke event. Some patients may have laboratory evidence supporting chronic renal insufficiency or endocrine disease (e.g., hyperadrenocorticism, hypothyroidism), but many are within normal limits. Laboratory findings are usually normal for FCE patients. For both brain infarcts and FCE, CSF results may be normal or reveal mild, nonspecific abnormalities (mild increase in cell count and protein concentration, xanthochromia). In one large, retrospective study of canine

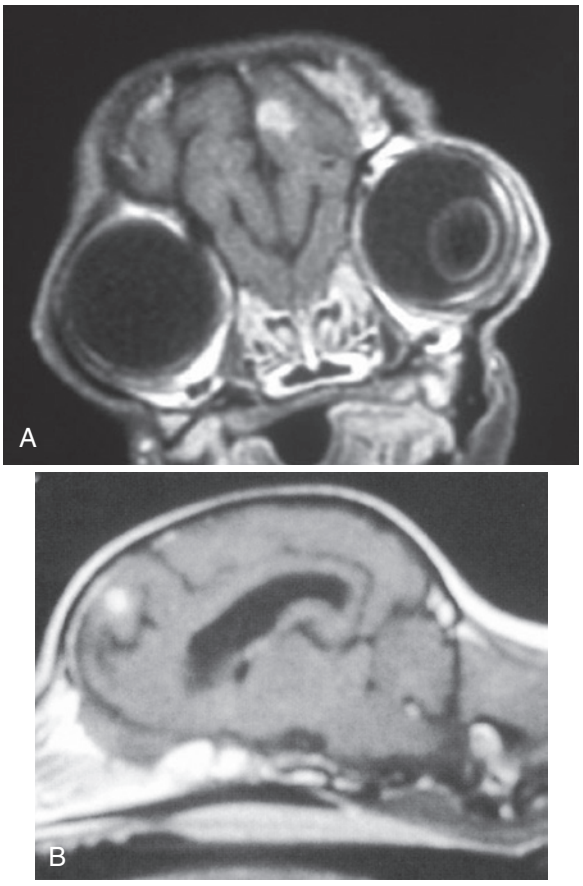

FIG. 43.5 (A) Axial and (B) sagittal magnetic resonance images (T1-weighted with contrast) of a dog with a focal hemorrhagic cerebral infarct.

FCE in which CSF results were available for 206 dogs, roughly half of the CSF results were within normal limits.[17]

DIFFERENTIAL DIAGNOSIS

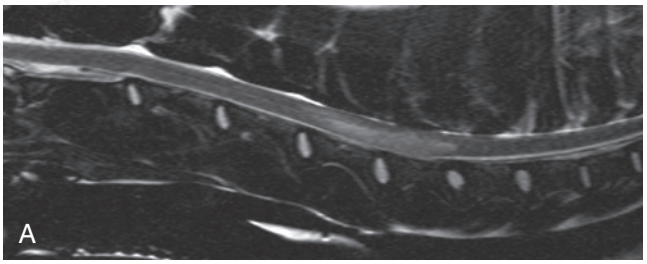
Differential diagnoses for brain infarcts include brain tumor, inflammatory/infectious disease (e.g., granulomatous meningoencephalomyelitis [GME]), and trauma. The most likely differential diagnosis for FCE is type I disc extrusion (particularly hydrated nucleus pulposus extrusion [HNPE]-type extrusions; see Chapters 40 and 41), followed by spinal neoplasia and inflammatory/infectious disease. In one study comparing dogs with presumptive FCE and dogs with HNPE, a number of distinguishing clinical features were identified (Box 43.2).[24]

MEDICAL MANAGEMENT

There is no specific medical management for either brain or spinal cord infarcts. For brain infarcts, medical management is directed at the underlying disease process if one is identified. For spinal cord infarcts, including FCE, medical management is focused on physical therapy and rehabilitation.

SURGICAL TREATMENT

Neither brain infarcts nor spinal infarcts are surgical disorders.



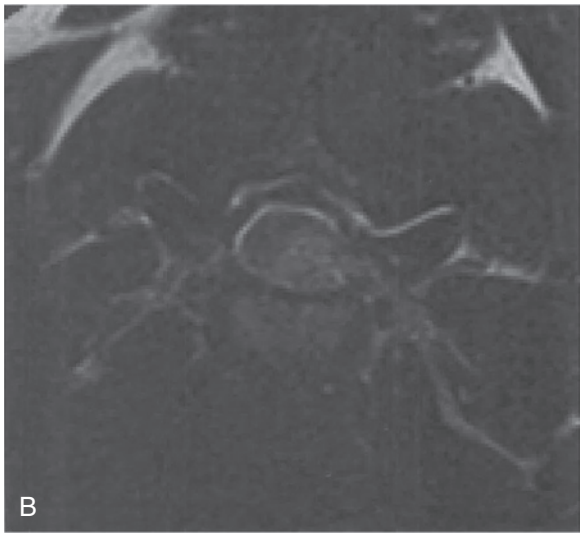


FIG. 43.6 (A) Midsagittal and (B) axial T2-weighted magnetic resonance images of the cervical region in a dog with fibrocartilaginous embolic myelopathy.

BOX 43.2 Clinical Features to Help Distinguish Between Fibrocartilaginous Embolic Myelopathy and Hydrated Nucleus Pulposus Extrusion

- English Staffordshire bull terriers are prone to FCE, whereas border collies are prone to HNPE.
- HNPE dogs are more likely to vocalize at onset of signs, compared with FCE dogs.
- HNPE dogs are more likely to have C1–C5 lesions than FCE dogs.
- HNPE dogs are more likely to exhibit spinal hyperesthesia on initial examination than FCE dogs.
- HNPE dogs are more likely to be ambulatory at time of hospital discharge than FCE dogs.
- FCE dogs are more likely to have L4–S3 lesions (and long-term fecal incontinence) than HNPE dogs.

Data from Fenn J, Drees R, Volk HA, et al. Comparison of clinical signs and outcomes between dogs with presumptive ischemic myelopathy and dogs with acute noncompressive nucleus pulposus extrusion. *J Am Vet Med Assoc.* 2016;249(7):767–775.

PROGNOSIS

The prognosis for dogs with focal brain infarcts is variable, but most have a guarded to fair prognosis for recovery of partial or full function. In one study of 33 dogs with brain infarcts, 10 dogs were euthanized; half of these were euthanized due to the severity of their underlying disease process rather than failure of their neurologic status to improve.[15] Another study of cerebellar infarcts also found a negative association between survival and presence of underlying systemic disease.[16] In a more recent retrospective study of 23 dogs with cerebellar infarcts, all dogs survived and were discharged from the hospital within 1 to 10 days of admission; in this case series, 12 dogs had concurrent underlying medical conditions. Although this study had only short-term follow-up, it does suggest that dogs with cerebellar infarcts tend to improve rapidly after initial infarction and most have a good prognosis for recovery.[21] The presence of an underlying or concurrent medical condition has also been associated with increased chance of repeat brain infarction within a 10-month period. The prognosis for functional recovery for dogs with FCE is somewhat variable, reflecting the range of lesion severity characteristic of this disease. In addition, recovery rates for these dogs vary considerably among published studies. Most of the recent literature suggests an overall favorable prognosis for dogs with FCE, whereas older literature is more pessimistic. For nonambulatory dogs, especially of the large and giant breeds, the prognosis for recovery is often guarded. Negative prognostic indicators reported include loss of deep pain perception (nociception), severe lower motor neuron damage, and owner reluctance to pursue prolonged physical therapy. There is some disagreement in the literature regarding the assertion that lower motor neuron damage portends a worse prognosis than upper motor neuron spinal cord damage in FCE cases. The degree of owner reluctance to pursue physical therapy is often associated with the size of the dog (e.g., prolonged physical therapy and bladder management for a paralyzed great Dane may not be feasible for many owners). In one report of 50 dogs,[25] 84% (42 dogs) had successful outcomes. In this study, the extent of the lesion as measured on MR images was predictive of outcome; dogs with a lesion length:vertebral length (C6 or L2, depending on whether the infarct was cervical or thoracolumbar) ratio (sagittal images) of 2 or less, or a cross-sectional (transaxial images) lesion area/spinal cord area percentage of less than 67%, were significantly more likely to recover, compared with dogs that had higher values for these parameters. Severity of neurologic signs at presentation was also significantly associated with a negative outcome in this study. The median time to maximal neurologic recovery for these dogs was 3.75 months. In a more recent retrospective study (2016) of 393 dogs with FCE, the overall prognosis was good to excellent, with 85% of dogs regaining the ability to walk unassisted; most patients reached this stage of neurologic improvement within 3 weeks, though persistent neurologic deficits were common in dogs that recovered the ability to walk unassisted (49.1%).[17] It appears that although FCE in dogs may be associated with a substantial level of morbidity and mortality, a large proportion of dogs may recover neurologic function following the infarct. Many of the cats diagnosed with FCE were euthanized shortly following presentation due to severity of neurologic deficits and presumption of a poor prognosis. Although the numbers of reported cats with ischemic myelopathy are much less than those described for dogs, the prognosis is generally favorable for recovery of neurologic function, whether the infarct is due to FCE or due to an underlying systemic condition (e.g., chronic renal failure, cardiomyopathy, hypertension). In one retrospective report of 19 cats with ischemic myelopathy due to a variety of suspected causes (FCE and underlying systemic disease), 79% of cases had a positive outcome.[20] In a similar retrospective case series in 11 cats, eight (73%) cats regained ambulatory function within 2 months of initial presentation.[18] In a retrospective report of eight older cats with cranial cervical cord infarcts associated with underlying disorders, all eight cats

recovered normal to near-normal neurologic status within 3 months of onset of clinical signs; three of these cats had suspected recurrent ischemic episodes.[19]

NONINFECTIOUS INFLAMMATORY DISEASE

DEFINITIONS

GME is a common, suspected autoimmune, noninfectious inflammatory disorder of dogs. **Necrotizing encephalitis** (NE) is a less common suspected autoimmune noninfectious inflammatory disorder of dogs, distinct from GME clinically and histopathologically. The umbrella terms **meningoencephalitis of unknown etiology (MUE)** and **meningoencephalitis of unknown origin** are sometimes used to encompass this group of disorders.[26]

GENERAL CONSIDERATIONS AND CLINICALLY RELEVANT PATHOPHYSIOLOGY

GME is characterized histologically by perivascular infiltrates of primarily mononuclear cells (lymphocytes, macrophages, and plasma cells) in the brain and/or spinal cord. The characteristic perivascular cellular infiltrates of GME both define the disease syndrome and account for the neurologic deficits. The underlying cause of this disease remains unknown; but there is evidence that GME is an autoimmune disorder, specifically a delayed-type (T cell–mediated) hypersensitivity reaction. Lesions predominate in the white matter with GME. There are three recognized clinical forms of GME: focal, multifocal (disseminated), and ocular. The ocular form is the least commonly encountered. In our experience, multifocal GME is the most common form of the disorder. NE includes two pathologically distinct disorders, referred to as necrotizing meningoencephalitis (NME) and necrotizing leukoencephalitis (NLE). These are also thought to be autoimmune disorders. Both NME and NLE are similar in that they are characterized by multiple cavitary necrotic nonsuppurative inflammatory brain lesions that involve both gray and white matter. The lesions in NME predominate in the cerebral cortex (gray matter). In NME, the lesions are typically found in the cerebrum, with consistent involvement of the leptomeninges. Extensive cerebral cavitations with a loss of demarcation between gray and white matter are typical for NME. NLE is characterized by similar lesions that often involve the brain stem in addition to cerebrum, with less consistent involvement of the leptomeninges and cerebral cortex (i.e., mainly white matter). Initial reports of these diseases in predisposed breeds led to the terms *pug encephalitis* or *pug/Maltese encephalitis* for NME and *Yorkshire terrier encephalitis* for NLE. It is believed that—considering the breed predilections of different types of meningoencephalitis of unknown origin—there is a genetic susceptibility component to these disorders in dogs.[27] Common genetic risk loci (for genes associated with regulation of immune system function) for the development of NME have been identified in several small dog breeds, including pugs, Maltese, and Chihuahuas.[28]

DIAGNOSIS

Clinical Presentation

Signalment

GME can affect any breed of dog of any age and either sex, but young to middle-aged (median age, 5 years) female dogs of small breeds (e.g., poodles, terriers) appear to be predisposed. NE also tends to occur in young, small-breed dogs, but a wide age range has been reported (approximately 7 months to 13 years). Pug and Maltese dogs are most commonly affected by NME, but other breeds reported with this disorder include Chihuahua, shih tzu, Pekingese, papillon, West Highland white terrier, Coton de Tulear, and Brussels griffon.[29] We also encountered a NME disorder in a Boston terrier. Yorkshire terriers appear to be the most common breed afflicted by NLE, but this disease may also affect other small-breed dogs. It is possible that NME and NLE represent variants of the same disease process. It is expected that more breeds will be reported with idiopathic NE. As with GME, the necrotic lesions observed on brain histopathology both account for the clinical signs of dysfunction and define the disease syndrome.

History

Multifocal GME is characterized by acute onset and rapid progression of CNS dysfunction, whereas dogs with focal GME tend to have a more insidious onset and slower progression of clinical signs. Common clinical complaints associated with GME include seizures, cerebellovestibular dysfunction, and cervical hyperesthesia. Isolated spinal cord dysfunction and visual deficits (optic neuritis) are uncommon clinical presentations of GME. Seizure activity is the most frequent clinical complaint with NE. The onset and progression of clinical signs of neurologic dysfunction with NE may be acute (disease course of ≤2 weeks) or chronic (disease course of 4–6 months). Clinical signs of forebrain dysfunction (e.g, seizures, circling, obtunded mental status, visual deficits with normal pupillary light reflexes, head-pressing) predominate. Neck pain is also common and may be due to the meningitis and/or the forebrain lesions. Yorkshire terriers with NLE often experience a chronic, progressive worsening of neurologic dysfunction over several months. In addition to clinical signs of forebrain dysfunction and neck pain, Yorkshire terriers with NLE often display clinical signs of brainstem dysfunction (e.g., central vestibular disease).

Physical Examination Findings

Physical examination findings are usually unremarkable, although some GME patients are febrile on presentation. Neurologic deficits are typically profound and reflect the location(s) of the lesions(s). Most GME patients have multifocal signs and often display central vestibular dysfunction. Most NE patients display primarily forebrain dysfunction.

Diagnostic Imaging

For both GME and NE, the preferred imaging modality is MRI, with CT being a poor second choice. The majority of GME patients have multifocal hyperintense (on T2-weighted and FLAIR sequences) lesions evident with variable contrast enhancement (T1-weighted with contrast). The contrast-enhancing lesions usually appear indistinct or "fuzzy" with blurred edges (Fig. 43.7). Some dogs with GME have secondary hydrocephalus evident on CT/MR images of the brain. MRI and CT findings have been described for NE as well. Lesions on MRI are usually iso- or hypointense on T1-weighted images, hyperintense on T2-weighted and FLAIR images, and usually non–contrast enhancing (Fig. 43.8). These cavitary lesions represent areas of brain necrosis.

Laboratory Findings

Bloodwork (CBC, serum biochemical panel) results are generally normal unless treatment with corticosteroids has begun prior to presentation, in which case one might see abnormalities such

FIG. 43.7 (A) Axial and (B) dorsal T1-weighted with contrast magnetic resonance images of a dog with granulomatous meningoencephalomyelitis.

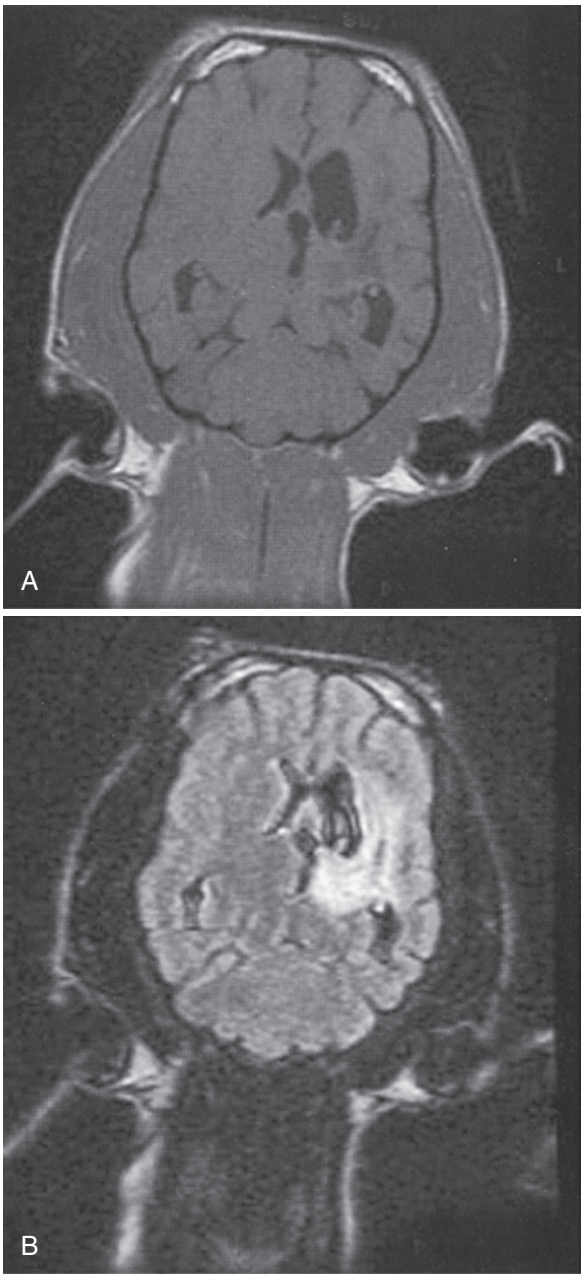

FIG. 43.8 (A) Dorsal T1-weighted and (B) fluid attenuation inversion recovery magnetic resonance images of a dog with necrotizing encephalitis.

as a stress leukogram or increased alkaline phosphatase concentration. CSF results for GME and NE are characteristically abnormal (see Box 37.4). A mainly mononuclear pleocytosis with a variable percentage of neutrophils (mean, approximately 20%) and elevated protein concentration is characteristic of GME. Uncommonly (≤10%), GME patients will have primarily neutrophilic or normal CSF results. In most cases of NE, a predominantly or exclusively mononuclear pleocytosis with elevated protein concentration is evident. The mononuclear cells in NME are usually primarily lymphocytic, whereas a mixture of lymphocytes and monocytes is usually seen in the CSF of NLE patients.

DIFFERENTIAL DIAGNOSIS

Differential diagnoses for GME and NE patients include brain tumor (especially if signs reflect a focal lesion), anomalous brain disorders (e.g., CLM, intracranial arachnoid cyst), brain infarct (if signs reflect a focal lesion), and infectious disease. The definitive diagnosis of GME and NE depends on histopathologic confirmation of the disease process. The tentative diagnosis is based on characteristic imaging and CSF results, in combination with supportive historical, signalment, and clinical presentation features.

MEDICAL MANAGEMENT

Although prednisolone remains a facet of the treatment of GME and NE, it should no longer be considered the mainstay of therapy for these disorders. In addition to prednisolone, therapies for

BOX 43.3 Drugs for Treatment of Granulomatous Meningoencephalomyelitis and Necrotizing Encephalitis

- Prednisolone: 1–2 mg/kg PO q12h
- Procarbazine: 25 mg/m^2 PO q24h
- Cyclosporine: 3–5 mg/kg PO q12h
- Cytosine arabinoside: 50 mg/m^2 SC q12h for 2 days (typically 400 mg/m^2 over 24 h CRI)
- Azathioprine: 2.0 mg/kg PO q24h
- Leflunomide: 2.0–4.0 mg/kg PO q24h
- Mycophenolate mofetil: 20 mg/kg PO q12h, reduce to 10 mg/kg PO q12h after 3–4 wk (anecdotally seems to be more effective for NE vs. GME)

CRI, Constant-rate infusion; *GME,* granulomatous meningoencephalomyelitis; *NE,* necrotizing encephalitis; *PO,* orally; *SC,* subcutaneous.

GME and NE include cyclosporine, cytosine arabinoside, procarbazine, azathioprine (AZA), leflunomide, and mycophenolate mofetil (MMF; Box 43.3). Myelosuppression is the most likely adverse effect from procarbazine, although hemorrhagic gastroenteritis may also occur. Potential side effects from cyclosporine use in dogs include vomiting, diarrhea, hyporexia, weight loss, gingival hyperplasia, papillomatosis, hypertrichosis, and excessive shedding. Side effects from cyclosporine use are generally minimal if plasma levels are within target ranges. Myelosuppression is also a potential concern with the use of cytosine arabinoside. This almost never occurs with the dosage protocols used for GME and NE patients. In general, when using these drugs (especially procarbazine) CBC should be checked weekly for the first month, then monthly to every 2 months thereafter to monitor for myelosuppression. The most common side effect of AZA is bone-marrow suppression, necessitating regular CBC examinations. Other potential side effects include gastrointestinal upset, pancreatitis, hepatotoxicity, and poor hair growth. It may take approximately 2 weeks from initiation of AZA for a clinical response to be apparent. The most likely adverse effects of MMF use are gastrointestinal (vomiting, hemorrhagic diarrhea); these effects are usually avoidable if the initial dose is reduced within 3 to 4 weeks. In our experience, MMF tends to be more effective for NE than for GME. Antiseizure drugs should be administered to GME and NE patients with seizure activity, preferably drugs that do not cause sedation or polyuria and polydipsia (see pp. 1339–1340). Combination therapy with several of these drugs may be necessary for initial disease control, with the drugs slowly weaned over time, if possible. Drug weaning should not be initiated until there is an obvious response to therapy; one drug should be weaned at a time, and changes should not be done more quickly than every 4 weeks. Dogs with controlled GME and NE typically do not become drug free but are often maintained on a low enough level of therapy to avoid the obvious side effects of therapy.

SURGICAL TREATMENT

Neither GME nor NE is a surgical disorder, but surgical biopsy may be considered in some cases.

PROGNOSIS

In recent years, the prognosis for GME has improved dramatically, coincident with the development of improved treatment protocols. The prognosis for NE is still poor, but anecdotally it appears to have improved to some degree with new drug protocols. Historically, survival times for multifocal GME dogs treated with glucocorticoids alone have ranged from approximately 2 weeks to 3 months, although more recent evidence suggests considerably longer survival times.[30] Nonetheless, because of the variable and often poor response to glucocorticoid therapy, as well as frequent glucocorticoid-related side effects, a number of immunosuppressive drugs have been evaluated as adjunctive treatment options for GME patients. The three most promising drug options are procarbazine, cytosine arabinoside, and cyclosporine. Survival times exceeding 12 months have been reported for each of these drugs. Additionally, the use of these drugs appears to allow for successive decreases in glucocorticoid dosages, thereby minimizing adverse side effects associated with steroid use. Procarbazine (25 mg/m^2 orally, once daily) is an antineoplastic drug that crosses the blood-brain barrier and has some specificity for T cells. The cytotoxic effects of procarbazine are thought to be primarily via methylation of DNA bases. In one study of presumptive GME dogs, the use of procarbazine as an adjunct to prednisone was associated with a median survival time of 14 months,[31] regardless of clinical form of GME (the majority were multifocal). In one report of 10 dogs with noninfectious encephalitis of undetermined etiology,[32] cytosine arabinoside treatment was associated with a median survival time of approximately 1.5 years. In one study of 10 dogs with presumptive GME treated with cyclosporine,[33] the median survival time was approximately 2.5 years. In one study of dogs with MUE treated with AZA and prednisone, the median survival time was approximately 5 years. In that study, dogs that exhibited a complete response to therapy had significantly longer survival times than those with a partial response and dogs that did not relapse had significantly longer survival times than those that did relapse.[34] In our experience, most dogs with GME respond well to combination therapy and do well for at least 2 to 3 years. The response to therapy and prognosis for dogs with NE appears to be less than that for dogs with GME. The prognostic literature for MUE in dogs focuses on long-term outcome, but there is little information regarding short-term outcome for this group of disorders. In one retrospective study of 116 dogs with MUE, 30 (26%) patients died within the first week of diagnosis, despite treatment; significant negative prognostic indicators included decreased mental status, presence of seizures, and increased percentage of neutrophils on CSF analysis.[35] Despite improvements in prognosis for dogs with GME and NE, there appears to be a substantial early mortality for patients with these disorders.

STEROID-RESPONSIVE MENINGITIS-ARTERITIS

DEFINITIONS

Steroid-responsive meningitis-arteritis (SRMA) is a suspected autoimmune disorder characterized by inflammation of the meninges and meningeal arteries. This disorder is also often termed *corticosteroid-responsive meningitis/arteritis, aseptic meningitis,* and *sterile meningitis.*

GENERAL CONSIDERATIONS AND CLINICALLY RELEVANT PATHOPHYSIOLOGY

This is a suspected autoimmune inflammatory disorder of the meninges and meningeal vasculature that tends to affect young

adult large-breed dogs. In some cases, patients with this disorder have concurrent autoimmune polyarthritis. This is most typically an acute disorder, but a less common, chronic form of the disease has been described. The chronic form of the disorder is suspected to be due to relapse and/or inadequate treatment of the acute form of the disease.

DIAGNOSIS

Clinical Presentation

Signalment

This usually occurs in young (<2 years old), medium- to large-breed dogs, and may be the most common type of meningitis encountered in veterinary practice. There are several breeds predisposed to this condition, including boxers, beagles, Bernese mountain dogs, Weimaraners, and Nova Scotia duck tolling retrievers.[36]

History

In the most common ("classic") form of SRMA, the history is typically an acute onset of severe cervical hyperesthesia accompanied by lethargy and a stiff gait. The chronic form of the disorder is typified by cervical hyperesthesia as well but also by signs of spinal cord dysfunction (e.g., ataxia and paresis).

Physical Examination Findings

In the acute form of SRMA, the overwhelming clinical sign is profound cervical hyperesthesia. These dogs tend to adopt a hunched posture and resist any neck movement. They are often febrile on presentation and often have evidence of hyperesthesia in other spinal locations on palpation. Dogs with the chronic form of SRMA are more likely to have neurologic deficits such as ataxia and paresis, consistent with a compressive myelopathy.

Diagnostic Imaging

Survey spinal radiographs should be obtained to rule out disorders such as discospondylitis and vertebral physitis. In acute cases of SRMA, MRI of the cervical spine is often performed to rule out other causes of a cervical myelopathy. The MR results are often normal but may show evidence of meningeal enhancement on T1-weighted with contrast sequences. More obvious lesions on MRI may be apparent in chronic SRMA cases because of suspected meningeal fibrosis.

Laboratory Findings

Bloodwork results are often normal, but may show a leukocytosis with a left shift, especially in acute SRMA cases. CSF results are usually dramatic in acute SRMA cases, with a marked polymorphonuclear pleocytosis (predominantly or exclusively nondegenerate neutrophils) and elevated protein concentration (see Box 37.4). In chronic SRMA cases, the CSF is often less dramatic (may be normal) and may be mainly mononuclear or a mixed cell pleocytosis with or without elevated protein concentration. Elevated IgA concentrations in serum and CSF are characteristic of SRMA. Several acute-phase proteins (e.g., C-reactive protein and alpha-2 macroglobulin) have also been found to be consistently elevated in SRMA dogs.

DIFFERENTIAL DIAGNOSIS

Differential diagnoses for SRMA include infectious meningomyelitis (particularly bacterial), discospondylitis, type I disc extrusion, and spinal neoplasia.

MEDICAL MANAGEMENT

Treatment with immunosuppressive doses of prednisone (2–4 mg/kg per day) usually results in rapid improvement in acute cases. Additional treatment with oral analgesics (e.g., tramadol) can also be considered. If there is concern about an infectious etiology, concurrent antibiotics can be coadministered for 2 to 4 weeks. These patients should be slowly weaned off the prednisone over a number of months (e.g., 3–6 months), but approximately half of these dogs will require some level of long-term immunosuppressive therapy; most of the dogs requiring such extended therapy can be weaned to a very low dose of drug. There are anecdotal reports of successfully using other immunomodulatory drugs for this disorder (e.g., AZA, cyclosporine, mycophenolate), especially for cases of relapse.

SURGICAL TREATMENT

SRMA is not a surgical disorder.

PROGNOSIS

The prognosis for control of clinical signs with the acute form of this disease is typically excellent with appropriate treatment. The prognosis for the chronic form of the disease is fair to guarded.

DISCOSPONDYLITIS

DEFINITIONS

Discospondylitis is an infection and inflammation of the intervertebral disc and adjacent vertebral end-plates and vertebral bodies. The cause is most commonly bacterial (usually *Staphylococcus* spp.), but occasionally it is fungal (e.g., *Aspergillus*).

GENERAL CONSIDERATIONS AND CLINICALLY RELEVANT PATHOPHYSIOLOGY

Discospondylitis is an infection of the intervertebral disc and its contiguous vertebrae, usually by coagulase-positive staphylococci (e.g., *Staphylococcus aureus, Staphylococcus pseudintermedius*). Other bacteria have been reported (e.g., *Streptococcus, Brucella*), as well as fungal organisms (e.g., *Aspergillus terreus, Aspergillus deflectus*). There is evidence to suggest that some dogs that develop discospondylitis may have defective immunocompetence as a predisposing factor. Infectious organisms may gain access to the disc space and vertebrae via a number of proposed mechanisms. Hematogenous spread is thought to be the most common mechanism, even though the primary source of infection is not always found. The urinary tract is generally thought to be the most likely source of bacterial infection. Foreign body migration is another potential mechanism for development of discospondylitis, the best example being plant awn migration. The barbs of plant awns favor migration through tissue. These awns may carry bacteria with them to the disc space and/or serve as a nidus for bacterial localization once they arrive at the disc space. Iatrogenic infection may develop following spinal surgery or paravertebral injection. This is considered to be the least likely mechanism for bacterial localization to the disc space and vertebrae. In one retrospective study of 372 dogs that underwent decompressive surgery for intervertebral dis herniation,

only eight (2.2%) dogs developed postoperative discospondylitis; risk of developing discospondylitis was significantly associated with body weights over 20 kg.[37] Although *Brucella canis* is an uncommon cause of canine discospondylitis, it has zoonotic potential; therefore the clinician should check for it (e.g., blood cultures, serology).

DIAGNOSIS

Clinical Presentation

Signalment

Discospondylitis is most commonly encountered in medium- to giant-breed male dogs of any age, but it has been reported in small-breed dogs as well as in cats. In one large retrospective study of dogs with discospondylitis,[38] older dogs were overrepresented, as were male dogs and purebred dogs (especially great Danes). The odds of having discospondylitis in this study were highest for dogs over 10 years of age.

History

Most dogs with discospondylitis display progressive clinical signs over at least several weeks, but some dogs develop signs acutely. Clinical signs are often nonspecific but usually include hyperesthesia associated with the spinal lesion(s). Dogs with lumbosacral discospondylitis tend to walk with a stilted pelvic limb gait. Decreased appetite, weight loss, depression, fever, and reluctance to move are other common nonspecific clinical features of this disease.

Physical Examination Findings

Most dogs with discospondylitis demonstrate evidence of hyperesthesia in the regions of the spinal lesions. Many dogs have no neurologic deficits or mild evidence of neurologic dysfunction (e.g., proprioceptive deficits with or without mild paresis). Some patients may be severely paretic or plegic. Dogs with discospondylitis may or may not exhibit systemic signs of disease such as lethargy, fever, and anorexia.

Diagnostic Imaging

Diagnosis of discospondylitis is usually based on characteristic radiographic findings with supportive historical and clinical features. Radiographs usually reveal collapse of the affected disc space(s), bony lysis in the end-plate regions of the affected disc space(s), and a variable component of bony proliferation and end-plate sclerosis (Fig. 43.9). These latter changes are often seen in chronic cases. A separate radiographic appearance, termed *vertebral physitis,* has also been reported, primarily in young dogs (<2 years of age). The majority of vertebral physitis cases have involved the lumbar vertebrae. In this condition, bony lysis seems to originate in the caudal physeal region of the vertebral body rather than the disc/end-plate region. Other clinical features of vertebral physitis appear to be indistinguishable from discospondylitis. Radiographic changes may lag behind clinical signs by as much as 2 to 4 weeks. A patient with normal radiographs and clinical features suggestive of discospondylitis may still have disease. Subtle lesions may also be missed if the radiographs are performed in the awake patient. In some cases, bone scintigraphy, CT, or MRI of suspected lesions may be valuable. Characteristic MRI features of discospondylitis have been described; these include hyperintense disc spaces and paravertebral soft tissues on T2-weighted and short tau inversion recovery images, heterogeneous contrast enhancement of affected disc spaces and end-plate regions, and hypointense affected vertebral bodies on T2-weighted images.[39]

FIG. 43.9 Lateral radiograph of a dog with discospondylitis at L7–S1.

Laboratory Findings

Bloodwork results are often normal, although leukocytosis is occasionally evident on a CBC. Some dogs have evidence of urinary tract infection on urinalysis. Bacteria may be cultured from the blood, urine, and/or affected disc spaces (fluoroscopically-guided needle or surgical aspirate); the reported success rate of such culture attempts varies but is approximately 50%. There is some evidence that culture of material obtained via needle aspiration of infected disc space(s) is more sensitive than culture of urine or blood.

DIFFERENTIAL DIAGNOSIS

Differential diagnoses for discospondylitis are primarily disc extrusion/protrusion and spinal neoplasia.

MEDICAL MANAGEMENT

Ideally, medical treatment of discospondylitis is guided by culture and antibiotic sensitivity testing of the offending organism. Because the organism is usually a *Staphylococcus,* first-generation cephalosporins or beta-lactamase–resistant penicillin drugs are often effective. In severely affected (e.g., paralyzed) patients, intravenous antibiotics should be administered for the first 5 to 7 days, after which oral antibiotics can be instituted. Concurrent treatment with antibiotics active against anaerobic bacteria should be considered, especially if there is minimal to no response to therapy within the first week of treatment. Antibiotic therapy has traditionally been recommended for at least several months. Discospondylitis patients usually require treatment well beyond several months. In one large retrospective study on canine discospondylitis,[38] the mean duration of antibiotic treatment was 53.7 weeks, suggesting that traditional recommendations regarding treatment duration may be too conservative. Analgesic drugs (e.g., oral codeine) may also be necessary. We have had success using oral Tylenol 4 with codeine in dogs with very

painful discospondylitis. Dosing of this drug is based on the codeine (1–2 mg/kg, every 6–8 hours), not the acetaminophen. If alanine aminotransferase or serum bilirubin increases, acetaminophen should be stopped immediately until one can determine if acetaminophen toxicity is taking place. Each Tylenol 4 tablet contains 60 mg of codeine.

NOTE Tylenol 3 contains 30 mg codeine and 300 mg acetaminophen; Tylenol 4 contains 60 mg codeine and 300 mg acetaminophen. Be careful not to overdose the acetaminophen.

Surgical intervention may be warranted in patients with vertebral instability or with compressive lesions identified with CT, MRI, or contrast radiography. Treatment of patients with *Brucella* infections typically entails a combination of tetracyclines and aminoglycosides. *B. canis* infections can be difficult to cure; it is prudent to recheck the patient after medical management. Infections with *A. terreus* and *A. deflectus* can be difficult or impossible to resolve. Itraconazole has been used extensively, but posaconazole and voriconazole probably offer a better chance for success. Combination with terbinafine might increase efficacy of these azoles.

SURGICAL TREATMENT

Although discospondylitis is considered primarily a medical disorder, surgical intervention may be necessary in some cases. In patients with deteriorating neurologic status despite appropriate medical therapy, or in nonambulatory patients, the possibility of a compressive lesion exists. Possibilities include instability resulting from end-plate and disc compromise, extruded/protruded disc in the vertebral canal at the site of infection, and infected material within the vertebral canal causing spinal cord compression. Dogs with radiographic evidence and severe and/or progressive neurologic deficits often have compressive lesions at the radiographic site of discospondylitis, consisting of a combination of pus and infected epidural fat. The infected epidural fat assumes a brown discoloration and compresses the spinal cord. In patients that are deteriorating or that present with severe neurologic dysfunction, myelography, CT, or MRI (preferably) should be performed to investigate for compressive spinal cord lesions. In one MRI study of 23 dogs with discospondylitis, 17 (74%) had evidence of a static compressive spinal cord lesion at the abnormal site; a significant correlation between the percentage of spinal cord compression and degree of neurologic impairment was found in this study.[39]

Preoperative Management

See Preoperative Management for each specific location of the spine affected (i.e., cervical, thoracolumbar, and lumbosacral) on pp. 1366, 1404, and 1428, respectively.

Anesthesia

Suggested anesthetic protocols for animals undergoing spinal surgery are provided on p. 1366.

Surgical Anatomy

Anatomic descriptions for each location of the spine affected (i.e., cervical, thoracolumbar, and lumbosacral) are provided on pp. 1366, 1404, and 1428, respectively.

Positioning

Refer to the surgical procedure chosen for recommendations for appropriate surgical positioning.

SURGICAL TECHNIQUE

See surgical technique descriptions for each specific location of the spine affected (i.e., cervical, thoracolumbar, and lumbosacral) on pp. 1367, 1405, and 1428, respectively.

SUTURE MATERIALS/SPECIAL INSTRUMENTS

Avoid using nonabsorbable multifilament sutures (e.g., silk) in infected surgical sites.

POSTOPERATIVE CARE AND ASSESSMENT

After surgery, these patients should be assessed as described on pp. 1374, 1409, and 1430. Antibiotics should be continued for a minimum of 4 to 6 weeks.

PROGNOSIS

Prognosis is generally favorable with bacterial discospondylitis, particularly in cases with no or mild neurologic deficits. Prognosis is more guarded in dogs with resistant bacteria and in dogs with severe neurologic deficits. Obvious clinical improvement is generally expected within the first week of antibiotic therapy. Follow-up radiographs of affected disc spaces every 1 to 2 months are recommended to monitor the progress of disease. Fungal (e.g., *Aspergillus* spp.) discospondylitis is associated with a poor prognosis because the infection is usually disseminated at the time of diagnosis.

Peripheral Nervous System Disorders and Diagnostic Techniques

An exhaustive discussion of the peripheral nervous system (PNS) abnormalities that affect dogs and cats is beyond the scope of this textbook and of little clinical use to the neurosurgeon. Much more important than distinguishing what specific disorder of the PNS is affecting a particular patient is the ability to distinguish that the patient has a PNS disorder rather than a myelopathy. Individually, most disorders of the PNS are not encountered frequently. However, as a group, surgeons deal with these diseases on a regular basis because they are often confused with either myelopathies or musculoskeletal disorders. The specific disorders covered in this chapter include acquired myasthenia gravis (MG), autoimmune polymyositis, polyradiculoneuritis, and tick paralysis.

MUSCLE AND NERVE BIOPSY

Position the patient in lateral recumbency and aseptically prepare the pelvic limb as you would for stifle surgery (see p. 37). Prior to making the skin incision, palpate for the peroneal nerve so that the nerve will be in the region of your surgical approach. Make a vertical skin incision caudal to the patellar ligament, from a few centimeters proximal to the level of the patella to a few centimeters distal to the tibial tuberosity. Make the incision approximately 2 cm caudal to the level used to access the stifle joint (see p. 1234). Use a blade or Metzenbaum scissors to expose the biceps femoris muscle and fascia. Pull up a portion of this muscle with DeBakey forceps and incise the muscle full thickness along its longitudinal striations using Metzenbaum scissors. Continue the incision until a digit can be placed beneath the muscle to palpate the underlying peroneal nerve. Using either a No. 11 blade or Metzenbaum scissors, remove a rectangular section of the biceps femoris muscle (at least 2 cm in length). Identify the underlying peroneal nerve and carefully free a segment of the nerve from surrounding fascia. Retract the edges of the incised biceps femoris muscle with Gelpi retractors to facilitate exposure of the common peroneal nerve (Fig. 44.1). Place a stay suture in the edge of the nerve at the proximal site of the planned biopsy, using 6-0 polydioxanone. While applying gentle tension to this suture, incise (with a new No. 11 blade) the nerve medial to the stay suture knot to begin the nerve biopsy. Do not remove more than one-third of the width of the nerve at the biopsy site. Using either the No. 11 blade or fine tenotomy scissors, remove a longitudinal strip of the peroneal nerve (1–3 cm, depending on patient size) for biopsy. If a distal neuropathy is suspected, procure a second biopsy specimen from the cranialis tibialis muscle. Close the site routinely.

SPECIFIC DISEASES

ACQUIRED MYASTHENIA GRAVIS

DEFINITIONS

Acquired MG is an autoimmune disorder of the neuromuscular junction in which autoantibodies are formed against nicotinic acetylcholine (ACh) receptors of skeletal muscle. The classic clinical manifestation of the autoantibody attack is skeletal muscle weakness, which worsens on repeated exertion.

GENERAL CONSIDERATIONS AND CLINICALLY RELEVANT PATHOPHYSIOLOGY

Acquired MG is a common autoimmune neuromuscular disorder of dogs that is rarely diagnosed in cats. Autoantibodies produced against the nicotinic ACh receptors of skeletal muscles impair neuromuscular transmission and produce weakness that worsens with exertion. Megaesophagus is a frequent feature of acquired MG in dogs because of the high proportion of skeletal muscle in the canine esophagus; but it is less common in affected cats. Several clinical forms of acquired MG have been identified, including focal, generalized, and acute fulminating. The thymus is believed to play an integral role in the initiation of the autoimmune response to ACh receptors, but the factors responsible for triggering the autoimmune response of acquired MG are still unknown.

DIAGNOSIS

Clinical Presentation

Signalment

There is a bimodal age distribution for acquired MG in both dogs and cats, with peak incidences at approximately 3 and 10 years of age. Both males and females are affected, although there may be a slight decreased tendency for sexually intact dogs to develop MG. Breeds most commonly afflicted with MG include German shepherds, golden retrievers, and Labrador retrievers. Other breeds with a relatively high risk for MG include Akitas, terriers, and German shorthaired pointers. Somali cats (related to Abyssinians) and Abyssinian cats are at risk for developing acquired MG.

History

Common historical complaints include difficulty swallowing, regurgitation (often described as vomiting by owners), ptyalism,

ABSTRACT

Dogs and cats with selected disorders of the peripheral nervous system (PNS) are sometimes perplexing, appearing similar to patients with spinal cord dysfunction. It is important that surgeons have a thorough understanding of salient features of the more commonly encountered PNS disorders, as well as having an understanding of pertinent diagnostic tests and treatment options. Performing a muscle or nerve biopsy may be necessary in some animals to assist in diagnosing PNS disorders.

KEYWORDS

Peripheral nervous system
muscle/nerve biopsy
acquired myasthenia gravis
myositis
polyradiculoneuritis

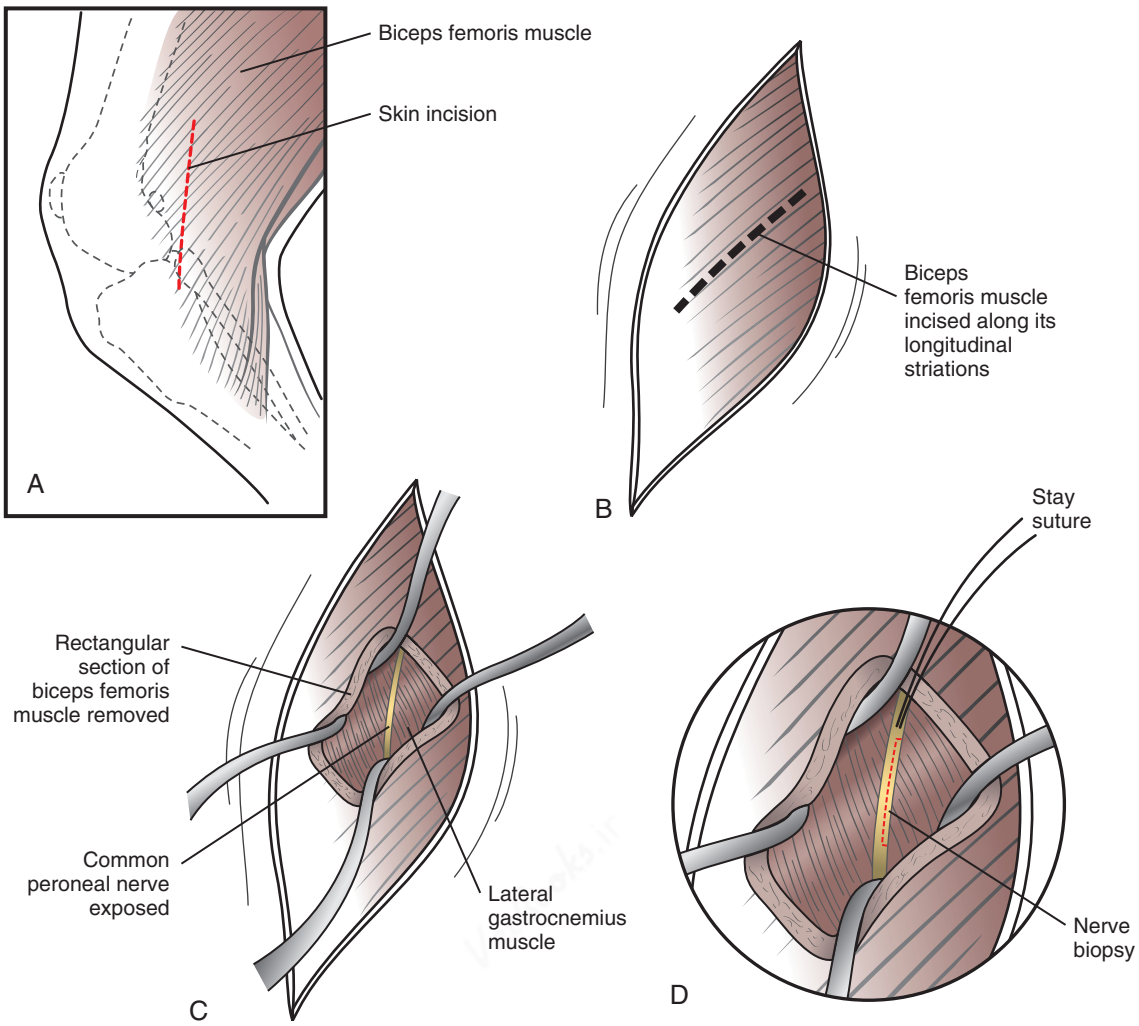

FIG. 44.1 Schematic illustration of the approach for a peroneal nerve biopsy. A section of biceps femoris muscle has already been removed for biopsy.

coughing, labored breathing, and limb muscle weakness (especially the rear legs). The specific constellation of clinical signs and time course of development reported by the owner varies with the clinical form of MG.

Physical Examination Findings

In addition to the historical complaints listed here, the nature of appendicular (limb) muscle weakness is variable in both distribution and severity. The clinical features of the different forms of acquired MG are provided in Box 44.1. Dogs and cats with MG typically do not have specific neurologic deficits but display varying levels of weakness. It is common for pelvic limb weakness to be the main (sometimes the only) clinical manifestation in dogs with MG; this feature often leads to misdiagnosis of MG as either a myelopathy or pelvic limb musculoskeletal disorder.

Diagnostic Imaging

Thoracic radiographs are recommended to look for megaesophagus, aspiration pneumonia, and mediastinal masses (i.e., thymoma). Mediastinal masses (typically thymoma) are much more common in cats with acquired MG than in myasthenic

BOX 44.1 Clinical Forms of Acquired Myasthenia Gravis in Dogs and Cats

Focal MG: No Clinical Signs of Appendicular (Limb) Muscle Weakness

Can present as megaesophagus, pharyngeal weakness, laryngeal weakness, and/or facial muscle weakness: each of these may be the sole presentation or may occur in any combination

Generalized MG: Clinical Signs of Appendicular Weakness

Typically see most (or all) of weakness in pelvic limbs, but thoracic limbs can be involved

Acute Fulminating MG: Rapid Onset and Progression of Severe Weakness

Profound focal and appendicular weakness
Acute onset, rapid progression to nonambulatory tetraparesis and respiratory distress
Usually fatal

MG, Myasthenia gravis.

dogs; in one retrospective study of 235 cats with acquired MG, 52% had evidence of a mediastinal mass (vs. 3.4% in dogs).[1]

Laboratory Findings

Bloodwork (complete blood cell count [CBC], serum biochemistry) is usually normal or may reflect a septic process in the face of pneumonia. The most definitive blood test for the diagnosis of acquired MG is an immunoprecipitation radioimmunoassay that quantitates serum autoantibodies directed against the ACh receptor. Concentrations of ACh receptor antibody above 0.6 nM/L and 0.3 nM/L are diagnostic for MG in dogs and cats, respectively. The edrophonium (Tensilon) challenge test may provide a presumptive diagnosis of MG in patients while awaiting results of an radioimmunoassay if it is clearly positive (i.e., the patient displays a clear improvement in strength shortly after administration of IV edrophonium). However, some dogs with various myopathies will also display increased strength after receiving edrophonium. Although the association between MG and thyroid disease is tenuous, thyroid status should be evaluated in MG patients.

DIFFERENTIAL DIAGNOSIS

Differential diagnoses include other PNS disorders (e.g., myopathies, neuropathies), musculoskeletal disease, and metabolic disorders (e.g., hypoglycemia, hypoadrenocorticism).

MEDICAL MANAGEMENT

Medical management of acquired MG in dogs and cats is typically either oral pyridostigmine or oral pyridostigmine plus immunosuppressive therapy (see Box 30.14). Treatment options for canine and feline MG are summarized in Box 44.2. Prednisolone often causes an initial worsening of weakness in dogs with MG; this adverse effect is potentially severe enough to justify avoiding prednisolone as an immunosuppressive agent for canine MG. A similar adverse effect of prednisolone treatment has not been documented for cats with acquired MG.

BOX 44.2 Treatment Options for Canine and Feline Acquired Myasthenia Gravis

Anticholinesterase Drugs
Pyridostigmine (preferred anticholinesterase drug)
Neostigmine (only if pyridostigmine is not available)

Immunosuppressive Drugs
Azathioprine (dogs)
Cyclosporine
Mycophenolate mofetil (dogs)

Thymectomy
Thymic hyperplasia (not evaluated in dogs and cats)
Thymoma (not until MG signs controlled)

Hormonal Therapy
Thyroxine if dog is hypothyroid

Nutritional Support
Elevated feedings
Gastrostomy tube feedings

MG, Myasthenia gravis.

SURGICAL TREATMENT

Acquired MG is not a surgical disorder. Dogs and cats (less likely) that frequently regurgitate may require a stomach tube to be placed either surgically (large dogs) or endoscopically (small dogs and cats) (see pp. 97 and 98). In cases of acquired MG with associated thymoma, the thymoma may need to be removed if it encroaches on neighboring anatomic structures. It is best to have clinical signs of MG stabilized prior to attempting thymoma removal.

PROGNOSIS

The prognosis for acquired MG is guarded overall. Many dogs will experience a spontaneous remission. In our experience, these tend to be younger patients. Spontaneous remission appears to be uncommon in cats with acquired MG.[1] Patients with persistent or recurrent pharyngeal/esophageal dysfunction have a poor prognosis because of the constant risk of aspiration pneumonia. The acute fulminating form of MG in dogs and cats is usually fatal.

AUTOIMMUNE POLYMYOSITIS

DEFINITIONS

Autoimmune polymyositis is an autoimmune inflammatory disease of unknown pathogenesis that primarily affects appendicular musculature.

GENERAL CONSIDERATIONS AND CLINICALLY RELEVANT PATHOPHYSIOLOGY

This is an idiopathic autoimmune disorder. There is usually no identifiable cause for the autoimmune response, but systemic lupus erythematosus, use of trimethoprim-sulfa drugs in Doberman pinschers, and thymomas (usually in conjunction with acquired MG) (see p. 951) have all been associated with the development of this condition.

DIAGNOSIS

Clinical Presentation

Signalment

Although any age or breed dog can be affected, most are middle-aged, large-breed dogs of either sex. Newfoundlands and boxers are overrepresented. Newfoundlands tend to develop the disease at a younger age than other breeds. A substantial number of boxers with polymyositis may develop the disorder as a preneoplastic condition.

History

Clinical signs can be acute or chronic. Historical complaints include generalized weakness (often worsened by exercise), stiff gait, generalized muscle atrophy, dysphonia, myalgia, regurgitation (megaesophagus may be present), fever, and muscle swelling.

Physical Examination Findings

Physical examination findings concur with historical complaints and are generally consistent with a generalized myopathic disorder. Some dogs with this disorder will have concurrent masticatory

myositis; this combination of autoimmune myopathies is referred to as overlap syndrome.

Diagnostic Imaging

Thoracic radiographs should be obtained to investigate for the presence/absence of megaesophagus. Abdominal ultrasonography may also be indicated if a paraneoplastic myopathy is suspected (especially in boxers).

Laboratory Findings

Basic bloodwork (CBC, serum biochemistry) is typically normal. Creatine kinase levels are typically elevated. Electromyographic examination typically reveals abnormalities, and muscle biopsy demonstrates myofiber necrosis, phagocytosis, and regeneration, with a nonsuppurative inflammatory infiltrate. Immunoglobulin localization to the sarcolemma may also be demonstrable immunohistochemically.

DIFFERENTIAL DIAGNOSIS

Differential diagnoses include infectious polymyositis (e.g., toxoplasmosis, neosporosis), preneoplastic/paraneoplastic myositis, and acquired MG.

MEDICAL MANAGEMENT

Treatment consists of oral prednisone therapy at immunosuppressive doses (e.g., 1–2 mg/kg, q12h) until clinical remission is achieved. If prednisone is ineffective or if it cannot be tapered because of disease recurrence, other immunosuppressive drugs (e.g., azathioprine, cyclosporine, mycophenolate mofetil) can be used.

SURGICAL TREATMENT

This is not a surgical disorder, but muscle biopsy is necessary for a definitive diagnosis.

PROGNOSIS

The prognosis is favorable in approximately 80% of cases. Relapses may occur with tapering or discontinuation of immunosuppressive drugs.

ACUTE IDIOPATHIC POLYRADICULONEURITIS

DEFINITIONS

Acute idiopathic polyradiculoneuritis is an idiopathic inflammatory disorder primarily involving both axons and myelin of ventral nerve roots; it occurs in dogs, and it is probably one of the most common polyneuropathies in this species. This disorder is similar to Guillain-Barré syndrome of people. It has been referred to also as **coonhound paralysis**.

GENERAL CONSIDERATIONS AND CLINICALLY RELEVANT PATHOPHYSIOLOGY

There is evidence that axonal loss is more prominent than demyelination in most dogs with polyradiculoneuritis. Demyelination is thought to be most severe in the ventral nerve roots in dogs with minimal myelin loss in the major nerve trunks. An autoimmune process is suspected, but the pathogenesis is uncertain. The term *coonhound paralysis* refers to those dogs with a history of being bitten or scratched by a raccoon shortly before developing clinical signs of disease. The term *idiopathic polyradiculoneuritis* refers to patients with an identical clinical disorder but with no possible exposure to raccoons. These two subcategories probably reflect the same disease syndrome, with the trigger for the inflammatory process being as yet unidentified in the latter subcategory. The typical clinical scenario for acute idiopathic polyradiculoneuritis describes a rapidly developing lower motor neuron (LMN) paresis/plegia, usually beginning in the pelvic limbs, and eventually involving the thoracic limbs.

DIAGNOSIS

Clinical Presentation

Signalment

There is a wide age range and no apparent sex predilection for this disorder. Certain breeds of coonhounds (e.g., Walker, black and tan, blue tick) are thought to be predisposed to this disease. However, one 2010 retrospective study found that the most common breed affected by this disorder is the Labrador retriever.[2]

History

The typical clinical scenario for acute idiopathic polyradiculoneuritis describes a rapidly developing LMN paresis/plegia, usually beginning in the pelvic limbs and eventually involving the thoracic limbs. Most affected animals will progress to being either nonambulatory tetraparetic or tetraplegic within 10 days of initial onset of clinical signs. It is fairly common for this stage of dysfunction to be reached within a 72-hour period of time. Development of life-threatening respiratory paralysis is a concern, especially in the more rapidly developing cases. Loss of voice (dysphonia, aphonia) is common, and some patients will also exhibit facial weakness.

Physical Examination Findings

In addition to the historical features described earlier, spinal reflexes are typically absent (with the exception of the perineal reflex, which is normal), muscles are hypotonic, and neurogenic atrophy develops quickly in recumbent patients. Proprioceptive placing reactions will be normal in those animals that still have enough motor ability to perform the efferent limb of these tests. These patients retain the ability to urinate and defecate, and they will readily eat and drink if the head is supported. Pain sensation also remains intact. In fact, these animals often seem hyperesthetic on limb manipulation, which may reflect the inflammatory nature of the disease.

Diagnostic Imaging

Thoracic radiographs are obtained to evaluate for atelectasis, aspiration pneumonia, the presence of megaesophagus, or metastatic lesions (i.e., paraneoplastic neuropathy).

Laboratory Findings

Bloodwork (CBC, serum biochemistry) is typically normal. Creatine kinase is usually normal but may be slightly elevated because of recumbency. Cerebrospinal fluid examination may demonstrate increased protein levels. Many, if not most, of these dogs will exhibit abnormal electromyographic activity with normal motor nerve conduction velocities. The patients often do not have enough functional axons to ambulate, but the remaining axons have essentially normal myelination.

DIFFERENTIAL DIAGNOSIS

Differential diagnoses include paraneoplastic polyneuropathy, tick paralysis, acquired MG, protozoan polyradiculoneuritis/polymyositis, and botulism (rare).

MEDICAL MANAGEMENT

There is no known effective medical therapy for this disorder. In one study evaluating treatment of dogs with acute idiopathic polyradiculoneuritis using human intravenous immunoglobulin, the median time to unassisted ambulation of intravenous immunoglobulin–treated dogs was 27.5 days compared with 75.5 days for untreated historical controls; however, this difference was not found to be statistically significant.[3]

SURGICAL TREATMENT

This is not a surgical disorder; however, muscle/nerve biopsy may be part of the diagnostic approach.

PROGNOSIS

The prognosis for full recovery is often favorable but can be prolonged, usually taking several weeks to months. Some patients develop life-threatening respiratory paresis/paralysis in the acute phase of the disease (usually those dogs whose signs progress rapidly over 72 hours) and may need to be mechanically ventilated. Nursing care, physical therapy, and proper nutrition are essential for recovery. In one retrospective study of 58 dogs with acute idiopathic polyradiculoneuritis, 88% (51 of 58 dogs) survived the disease.[2]

TICK PARALYSIS

DEFINITIONS

Tick paralysis is an acute-onset, rapidly progressive LMN paralysis caused by a salivary neurotoxin produced by certain species of ticks. The neurotoxin interferes with neuromuscular transmission and has a neuropathic effect as well.

GENERAL CONSIDERATIONS AND CLINICALLY RELEVANT PATHOPHYSIOLOGY

In North America, tick paralysis is caused by *Dermacentor* species and affects only dogs. In Australia, a more severe form of tick paralysis affects dogs and cats; it is caused by a salivary neurotoxin carried by *Ixodes* ticks. The incidence of tick paralysis is highest in the summer months. After entering the circulation, the neurotoxin reaches the neuromuscular junctions and interferes with ACh release; the toxin is also believed to affect nerve transmission. A single tick can cause clinical signs, and the development of clinical dysfunction occurs approximately 5 to 9 days after tick infestation.

DIAGNOSIS

Clinical Presentation

Signalment

Any age, breed, and either sex of dog can be affected by tick paralysis.

History

The typical history is that of acute onset and rapidly progressive (24–72 hours) flaccid tetraplegia starting in the pelvic limbs.

Physical Examination Findings

Dogs with tick paralysis have a LMN paresis/paralysis of all four limbs. Spinal reflexes are depressed to absent, cranial nerves are usually normal (mild facial nerve paresis may occur), and pain sensation is normal; there is no evidence of hyperesthesia, and urinary/fecal continence is preserved. Dogs usually maintain a tail wag.

Diagnostic Imaging

Thoracic radiographs are typically normal. Megaesophagus may occur with the Australian version of tick paralysis caused by *Ixodes holocyclus*.

Laboratory Findings

Bloodwork (CBC, serum biochemistry) is typically normal.

DIFFERENTIAL DIAGNOSIS

Differential diagnoses include acute idiopathic polyradiculoneuritis, acute fulminating MG, and botulism (rare).

MEDICAL MANAGEMENT

Medical management of tick paralysis is removal of causative ticks. This may require shaving the dog to identify all the ticks and may also require the administration of an acaricide to ensure all ticks are dead. The tick sometimes "hides" in the ear canal, so it is important to check both ear canals thoroughly.

SURGICAL TREATMENT

This is not a surgical disorder.

PROGNOSIS

In North America, tick removal is generally curative, with recovery occurring within 1 to 3 days of removal. Tick paralysis caused by the Australian ixodid tick *I. holocyclus* is often fatal, even after tick removal.

    techniques for, 521, 521*f*–522*f*
Abdominal incision, draping for, 39, 39*f*
Abdominal surgery, 512–539
  for abdominal exploration, 517–518, 517*b*
  abdominal wall closure in, 517–518
  anesthetic considerations with, 513, 514*t*
    in septic patient, 515*t*–516*t*
    with shock or debilitation, 513
  antibiotics for, 513
  complications of, 518
  definitions for, 512
  healing of abdominal wall after, 518
  for hemoperitoneum, 535–538
  incisions for, 513
  indication for, 512
  for inguinal, scrotal, and femoral hernias, 522–527
  for peritonitis, 527–535
  postoperative care and assessment after, 518, 518*f*
  preoperative concerns with, 512–513
  special age considerations with, 518
  surgical anatomy for, 513, 513*f*
Abdominal surgery *(Continued)*
  surgical sponges in, 516*b*
  suture materials and special instruments for, 518
  techniques for, 513–517
    paracostal celiotomy as, 517
      abdominal wall closure for, 518
    ventral midline celiotomy as
      in cats and female dogs, 516, 516*f*
      in male dogs, 516–517, 516*f*
  for umbilical and abdominal hernias, 518–522
Abdominal wall
  closure of, 517–518
  healing of, 518
  surgical anatomy of, 520
Abdominocentesis, for peritonitis, 531, 534
Abducent nerve, 1325, 1325*t*
Abnormal activity, in electromyography, 1316, 1317*t*
Abrasion(s), 183
Abrasion arthroplasty, for medial compartment disease, 1185
Abscess(es)
  anal sac. *see* Anal sac infection.
  anorectal. *see* Perianal fistulae.
  hepatic
    defined, 563
    diagnosis of, 564
    differential diagnosis of, 564
    general considerations and clinically relevant pathophysiology of, 563–564
    medical management of, 564–565, 565*b*
    prognosis for, 565–566
    surgical treatment of, 565
  pancreatic, 606–609
    definitions for, 606–607
    diagnosis of, 607–608, 607*f*, 608*b*
    differential diagnosis of, 608
    general considerations and clinically relevant pathophysiology of, 607, 607*b*, 607*f*
    medical management of, 608
    prognosis for, 609
    surgical treatment of, 608, 609*b*
  prostatic, 763*t*, 764–768
    definitions for, 764
    diagnosis of, 765–766
      history in, 765, 765*b*
      imaging in, 765, 765*b*
      laboratory findings in, 765–766, 766*b*
      physical examination findings in, 765, 765*b*
      signalment in, 765
    differential diagnosis of, 763*t*, 766
    general considerations and clinically relevant pathophysiology of, 764–765, 765*b*
Abscess(es) *(Continued)*
    medical management of, 766, 766*f*
    prognosis for, 767–768
    surgical treatment of, 766–767
      anatomy for, 766
      anesthesia for, 766
      complications of, 767, 767*b*
      positioning for, 766–767
      postoperative care and assessment after, 767
      preoperative management of, 766
      surgical technique for, 767, 767*f*
  pulmonary, 903–905
  renal (intrarenal) and perirenal (perinephric), 675–677
    complications of, 677
    definitions for, 675
    diagnosis of, 676
    differential diagnosis of, 676
    general considerations and pathophysiology of, 676

    postoperative care and assessment of, 677
    prognosis for, 677
    special age considerations for, 677
    surgical technique for, 677
    surgical treatment of, 676
    suture materials and special instruments for, 677
Absorbable skin staples (Insorb), 67–68
Absorbable sutures, 61–62, 63*t*
  monofilament, 62, 63*t*
  multifilament, 62, 63*t*
  organic, 61–62
  for skin wounds, 190
  synthetic, 61–62
Absorbent bandages, 188
Absorbent cotton, for intermediate layer of bandage, 200–201
ABWA (alcohol-based water-aided) solutions, for surgical scrub, 44–46
ABWL (alcohol-based waterless) solutions, for surgical scrub, 44–46
Accessory nerve, 1325–1328, 1325*t*, 1328*f*–1329*f*
Accessory pancreatic duct, 604
Accessory process, 1404–1405, 1405*f*
Accuzyme, for débridement, 185–186
Acell Vet (porcine bladder extracellular matrix dressing), 197*t*–198*t*
Acemannan (Carravet), for wound healing, 187
Acepromazine
  for brain surgery, 1342
  for premedication, 125
  for tracheal collapse, 870
Acetabular fracture, 1099–1102
  classification of, 1099
  definitions for, 1099

Acetabular fracture *(Continued)*
diagnosis of, 1099
differential diagnosis of, 1099
general considerations and pathophysiology of, 1099
medical management of, 1099
prognosis for, 1102
surgical treatment of, 1099–1100
anesthesia for, 1100
approach via trochanteric osteotomy for, 1100, 1101*f*
bone plates and screws for, 1100, 1102*f*
complications of, 1102
positioning for, 1100
postoperative care and assessment after, 1101
preoperative management of, 1100
surgical anatomy for, 1100
suture materials and special instruments for, 1100–1101
Acetabulectomy, for bone neoplasia, 1305
Acetabulum, 1100
Acetazolamide
for Chiari-like malformation, 1356
for congenital hydrocephalus, 1349, 1349*t*
Acetic acid, as wound cleanser, 189
Achalasia, cricopharyngeal, 391–394
complications of, 394
definition for, 391
diagnosis of, 392
clinical presentation in, 392
imaging in, 392
laboratory findings in, 392
physical examination findings in, 392
differential diagnosis of, 392
general considerations and clinically relevant pathophysiology of, 391–392
medical treatment of, 392
postoperative care and assessment of, 394
prognosis for, 394
surgical technique for, 393–394, 394*f*
surgical treatment of, 393
anesthesia for, 393
positioning for, 393
preoperative management of, 393
surgical anatomy for, 393, 393*f*
Achilles tendon avulsion, 1285
Achilles tendon complex, orthopedic examination of, 963, 964*f*
Achilles tendon rupture, 1284–1286
definitions for, 1284
diagnosis of, 1284–1285, 1284*f*
differential diagnosis of, 1285
general considerations and clinically relevant pathophysiology of, 1284
medical management of, 1285
postoperative care of, 1286, 1286*f*
prognosis for, 1286
surgical treatment of, 1285
Acid injuries, 242
Acid-base abnormalities, 27
with renal disease, 650
Acne, interdigital, 250
treatment of, 250
Acral lick dermatitis, 248–249, 248*f*
treatment of, 249
Acral pruritic nodule, 248–249, 248*f*
treatment of, 249
Acromion, 1049*f*
Acropruritic granuloma, 248–249, 248*f*
treatment of, 249
Acrylic splints
in linear external fixators, 1002
for mandibular and maxillary fractures, 1041–1042, 1041*b*, 1043*f*
Acrylic-pin external fixation systems, 999–1000, 1000*f*
ACTH (adrenocorticotropic hormone) stimulation test, 592, 592*b*
Acticoat (nanocrystalline silver dressing), for burns, 240*f*
Acticoat (silver-impregnated dressings), 197*t*–198*t*, 200
Actinomyces spp., pyothorax due to, 948*t*, 949
Actiprep, for sterile skin preparation, 38–39, 38*t*
Actisorb (activated charcoal dressings), 197*t*–198*t*, 200
Actisorb (silver-impregnated dressings), 197*t*–198*t*, 200
Activated charcoal dressings, 197*t*–198*t*, 200
Active drains, 191
closed, 191, 191*f*
open, 191*f*
for small spaces, 191–192, 192*f*
Acupuncture, 140–157, 155*b*–156*b*
Acupuncture-like TENS, 114
Acute abdomen
defined, 512
preoperative management of, 512–513
Acute correction, 1079
Acute distraction, 1079
Acute idiopathic polyradiculoneuritis, 1463–1464
Acute immunologic reactions, 34
Acute kidney injury (AKI)
anesthetic considerations with, 651, 652*t*–653*t*
defined, 650
preoperative management of, 650
Acute renal failure (ARF), 650
Acute trauma patient, anesthetic considerations for thoracotomy of, 919*t*–920*t*
"Acute-on-chronic" disc rupture, 1375
Acyanotic tetralogy, 815
AD (Alzheimer disease), cognitive dysfunction syndrome and, 1444
Adamantinoma, 352, 356
Adaptic (petroleum-impregnated) dressing, 196, 197*t*–198*t*
Addison disease, 586
Adductor muscle, 520*f*, 686*f*
Adenocarcinoma(s)
anal sac apocrine gland, 490
of ceruminous gland, 325, 326*f*
colorectal, 475
defined, 430
endometrial, 751
nasal, 875*f*
Adenocarcinoma(s) *(Continued)*
pancreatic, 613
of pancreatic islets. *see* Insulinomas.
perianal gland, 489–490
of small intestine, 456, 456*f*
uterine, 751
Adenohypophysis, 597
Adenoma(s)
adrenal
defined, 590
differential diagnosis of, 592, 593*b*
general considerations and clinically relevant pathophysiology of, 597
history of, 590–591
medical management of, 593, 593*b*
surgical treatment of, 593–596
aortic body, 823
cholangiocellular, 566
hepatocellular, 566
pancreatic. *see* Insulinomas.
parathyroid, 625
perianal, 489
pituitary, 597–599
complications of, 599
definitions for, 597
diagnosis of, 597–598, 597*b*, 598*f*
differential diagnosis of, 598
general considerations and clinically relevant pathophysiology of, 597
macroadenoma as, 597, 598*f*
microadenoma as, 597
prognosis for, 599
surgical treatment of, 598–599
anatomy for, 599, 599*f*
anesthesia for, 599
postoperative care and assessment after, 599, 599*b*
preoperative management of, 599
suture materials and special instruments for, 599
technique for, 599
sebaceous, 273
thyroid, 619*f*
Adenomyosarcoma, embryonal, 673
ADH. *see* Adrenal-dependent hyperadrenocorticism.
Adherent dressings, 195, 197*t*–198*t*
Adherent film contact layer, 195–196, 197*t*–198*t*
Adhesive dressings, 197*t*–198*t*
skin-protectant film or skin sealant, 195–196, 197*t*–198*t*
transparent vapor-permeable film, 200
Adjustable sutures, for skin stretching and expansion, 207–208, 209*f*
Adrenal adenoma
defined, 590
differential diagnosis of, 592, 593*b*
general considerations and clinically relevant pathophysiology of, 597
history of, 590–591
medical management of, 593, 593*b*
surgical treatment of, 593–596
Adrenal carcinomas
defined, 590
differential diagnosis of, 592, 593*b*

Adrenal carcinomas *(Continued)*
general considerations and clinically relevant pathophysiology of, 597
history of, 590–591
medical management of, 593, 593*b*
surgical treatment of, 593–596
Adrenal cortex, 593
Adrenal gland, 587
definitions for, 586
healing of, 589
mineralized, 591, 591*f*
surgery of, 586–599
anesthesia for, 586–587
antibiotics for, 587
complications of, 589–590
postoperative care and assessment after, 587*b*, 589
preoperative management of, 586, 587*b*
special age considerations with, 590
surgical anatomy for, 587, 587*f*
surgical technique for, 587–589
suture materials and special instruments for, 589
Adrenal medulla, surgical anatomy of, 587
Adrenal neoplasia, 590–597
definitions for, 590
diagnosis of, 590–592
diagnostic imaging in, 591–592, 591*b*–592*b*, 591*f*–592*f*
history in, 590–591
laboratory findings in, 592, 592*b*
physical examination findings in, 591
signalment in, 590
differential diagnosis of, 592, 593*b*
general considerations and clinically relevant pathophysiology of, 590, 590*b*
medical management of, 593, 593*b*
prognosis for, 597, 597*b*
surgical treatment of, 593–596
anesthesia for, 594–596, 595*t*–596*t*, 596*b*
intraoperative considerations for, 595*t*–596*t*
postoperative care and assessment after, 595*t*–596*t*, 597
preoperative management of, 594, 594*b*, 595*t*–596*t*
suture materials and special instruments for, 596–597
technique for, 596
Adrenal-dependent hyperadrenocorticism (ADH)
diagnosis of
imaging in, 591
laboratory findings in, 592
medical management of, 593
preoperative management of, 586
tumors with, 590*b*
Adrenalectomy, 587–588
defined, 586
laparoscopic, 588–589
postoperative care and assessment after, 589
via midline abdominal approach, 588, 588*f*
via paralumbar approach, 588, 588*f*–589*f*
Adrenaline (epinephrine)
for cardiac disease, 789*b*
for inflow occlusion, 793*b*
for peritonitis, 533*b*
for pheochromocytoma, 595*t*–596*t*
Adrenocortical insufficiency
anesthesia with, 586–587
preoperative management of, 586, 587*b*
Adrenocortical tumors. *see* Adrenal adenoma; Adrenal carcinomas.
Adrenocorticotropic hormone (ACTH) stimulation test, 592, 592*b*
"Adult" stem cells, 970
Advancement flaps, 218
bilateral (bipedicle, H-plasty), 215, 216*f*
H-plasty pedicle, for eyelid mass, 275, 276*f*
for square and rectangular defects, 215, 216*f*
unilateral (single-pedicle), 216*f*
V-to-Y plasty, 210, 212*f*
AFAST (abdominal focused assessment with sonography for trauma), 29, 29*b*
Age-related differences, in hematologic and biochemical values, 26*b*
Aglepristone (Alizine, Alizin)
for pregnancy prevention or termination, 729*b*
for pyometra, 757*b*
Air flow, in operating room, 21
Airborne sources, of contamination, 1
AKI (acute kidney injury)
anesthetic considerations with, 651, 652*t*–653*t*
defined, 650
Alanine aminotransferase (ALT), high, 28*t*
Alar ligaments, 1368*f*
Albumin
in colloid solutions, 33
consequences of hypoalbuminemia and, 33*b*
human serum, 32*t*, 33
low, 28*t*
Albuminocytologic dissociation, 1322
Alcohol
as disinfectant, 5*t*
for sterile skin preparation, 38–39, 38*t*
Alcohol rubs, for surgical scrub, 44, 44*b*
Alcohol-based solutions
for sterile skin preparation, 38–39, 38*t*, 39*b*
prevention of pooling of, 39*b*
for surgical scrub, 44–46, 46*t*
Alcohol-based surgical hand rub, 44, 44*b*
Alcohol-based water-aided (ABWA) solutions, for surgical scrub, 44–46
Alcohol-based waterless (ABWL) solutions, for surgical scrub, 44–46
Alertness, 1323, 1324*t*
Alfaxalone, 127*t*–131*t*, 134
for brain surgery, 1340
for extrahepatic biliary surgery, 583*b*
Algidex AG (maltodextrin), for wound healing, 187
Algidex AG (silver-impregnated dressings), 197*t*–198*t*, 200
Alginate silver (Silvercel, Algidex AG), for burns, 239–240
Alizine (aglepristone)
for pregnancy prevention or termination, 729*b*
for pyometra, 757*b*
Alkali injuries, 242
Alkaline phosphatase, high serum, 28*t*
Allantoin, for wound healing, 187
Alligator jaw forcep, 161
Allis tissue forceps, 54, 55*f*
Allogeneic stem cell, 971
Allografts, 232–233
bone. *see* Bone allografts.
Allopurinol (Zyloprim), for urinary calculi, 705*b*
Aloe vera
for burns, 239–240
for wound healing, 187
Alpha-2 agonists, 144
for premedication, 127*t*–131*t*, 132
ALT (alanine aminotransferase), high, 28*t*
Alveolar artery, mandibular, 333, 334*f*
Alveolar hypoventilation, after cardiac surgery, 797
Alveolar oxygen tension (PAO_2), after cardiac surgery, 797
Alzheimer disease (AD), cognitive dysfunction syndrome and, 1444
Amantadine, 148*t*–149*t*, 151
Ameloblastomas, 352, 356
Ameroid constrictors, for portosystemic shunts, 555–556, 555*f*
placement of, 558, 558*b*
Amikacin (Amiglyde-V), 81*t*, 82
for aspiration pneumonia, 343*b*, 367*b*
for biliary disease, 572*b*
for hepatic abscess, 565*b*
for *Nocardia* infection, 950*b*
for perineal, rectal, or colonic surgery, 467–468, 468*b*
for peritonitis, 531, 531*b*
postoperative, 449*b*
for pyothorax, 948*t*
Aminoglycosides, 82
for perineal, rectal, or colonic surgery, 467–468
Aminopenicillins, 80
Aminophylline
for aspiration pneumonia, 367*b*
for electrical injury, 241
for tracheal collapse, 871*b*
Amiodarone
for cardiac disease, 789*b*
for gastric dilatation-volvulus, 425*b*
Amitriptyline, 148*t*–149*t*, 151
Amlodipine, for hyperaldosteronism, 593
Ammonia tolerance test (ATT), with portosystemic shunt, 554
Ammonium acid urate calculi, 701
treatment and prevention of, 702*t*
Amoxicillin (Amoxi-Tabs, Amoxi-Drops, Amoxi-Inject), 80
for *Actinomyces* infection, 950*b*
after foreign body removal, 166
for biliary disease, 572*b*
for Lyme disease, 1150, 1150*b*
for oral surgery, 333*b*
for tracheal collapse, 871*b*
for upper respiratory infection, 838*b*

Amoxicillin plus clavulanate (Clavamox), 81*t*
for hepatic abscess, 565*b*
for pyometra, 757*b*
for renal surgery, 653*b*
for reproductive disorders, 726*b*
for septic arthritis, 1140*t*
Ampicillin (Omnipen, Principen), 80
for aspiration pneumonia, 343*b*, 367*b*
for gastric dilatation-volvulus, 421*b*
for liver surgery, 543*b*
for perineal, rectal, or colonic surgery, 467–468, 468*b*
for peritonitis, 531, 531*b*
postoperative, 449*b*
for portosystemic shunts, 555, 555*b*
for pyometra, 757*b*
for pyothorax, 948*t*
for renal surgery, 653*b*
for reproductive disorders, 726*b*
for tracheal collapse, 871*b*
for upper respiratory infection, 838*b*
Ampicillin plus sulbactam (Unasyn), 81*t*
for hepatic abscess, 565*b*
for pyometra, 757*b*
for reproductive disorders, 726*b*
Amplatzer Canine Duct Occluder, for patent ductus arteriosus, 802–803
Amplatzer Septal Occluder, for atrial septal defect, 814, 814*f*
Amplatzer Vascular Plugs, for patent ductus arteriosus, 802–803, 803*f*
Amputation
for bone neoplasia, 1303–1305
coxofemoral disarticulation, 1303–1304, 1306*f*
forequarter, 1303, 1304*f*–1305*f*
hemipelvectomy as, 1303, 1303*f*
midfemoral, 1305, 1307*f*
of digit, 262, 262*f*–263*f*, 1091, 1091*f*
fusion podoplasty and, 265
of paw, 263–265, 264*f*
Amrinone (Inocor), for cardiac disease, 789*b*
Amyotrophic lateral sclerosis (ALS), degenerative myelopathy and, 1447
Anal canal, 484
Anal neoplasia, 489–493
definition for, 489
diagnosis of, 490–491
clinical presentation in, 490, 490*b*
imaging in, 490–491
laboratory findings in, 491
physical examination findings in, 490, 490*b*, 490*f*
differential diagnosis of, 491
general considerations and clinically relevant pathophysiology of, 489–493, 489*b*–490*b*
medical management of, 491
postoperative care and assessment after, 492, 492*b*
prognosis for, 493
surgical technique for, 492, 492*f*
surgical treatment of, 491–492
anesthesia for, 491
positioning for, 492
Anal neoplasia *(Continued)*
preoperative management of, 491, 491*b*
surgical anatomy for, 492
Anal prolapse. *see* Rectal prolapse.
Anal reflex, 1336, 1336*f*
Anal sac abscess. *see* Anal sac infection.
Anal sac apocrine gland adenocarcinomas, 490
Anal sac impaction. *see* Anal sac infection.
Anal sac infection, 493–496
complications of, 496
definition for, 493
diagnosis of, 493–494
clinical presentation in, 493
imaging in, 494
laboratory findings in, 494

anesthesia for, 494
positioning for, 494
preoperative management of, 494
surgical anatomy for, 494
Anal sac tumors, 487*b*, 489
Anal sacculectomy, 487, 487*b*
complications of, 489
defined, 482
incontinence after, 494*b*
surgical techniques for
closed, 495*f*
open, 495, 496*f*
Anal sacculitis. *see* Anal sac infection.
Analgesia
multimodal, 144–151, 148*t*–149*t*
alpha-2 agonists in, 144
amantadine in, 148*t*–149*t*, 151
amitriptyline in, 148*t*–149*t*, 151
Bier block in, 152
brachial plexus blocks in, 152
coccygeal epidurals in, 155
cranial cruciate surgery local blocks in, 153
dental blocks in, 151
epidural catheter in, 154–155, 155*b*
epidurals in, 153–154, 153*t*, 154*b*
femoral/sciatic nerve blocks in, 153
gabapentin in, 148*t*–149*t*, 151
intercostal nerve blocks in, 152
local, 144–150
for regional techniques, 151–155
maropitant in, 148*t*–149*t*, 151
NSAIDs in, 150, 150*b*
opioids in, 144, 149*t*
piprants in, 150–151
retrobulbar blocks in, 152
RUMM nerve blocks in, 152–153
preemptive, 331
Anaplasma phagocytophilum, polyarthritis due to, 1149
Anaplasmal polyarthritis, 1149
Anaplastic carcinomas, pulmonary, 900
Anastomosis(es)
intrapelvic urethral, 686–687, 687*f*, 689*f*
of large intestine, 470–471
stapled, 471
sutured, 471
of small intestine, 440–447
defined, 433
stapled, 444–447, 444*b*
inverting end-to-end, 444, 446*f*
side-to-side or functional, 444–447, 446*f*
triangulating end-to-end, 444, 445*f*
sutured, 440–444, 442*f*
with intestinal segments of disparate size, 440–441, 442*f*
modified simple continuous pattern for, 441–443, 443*f*
tracheal resection and, 844–845, 846*f*
complications with, 849
defined, 833
postoperative care after, 848
ureteral, 659–660, 661*f*–662*f*, 694, 696*f*
Ancef. *see* Cefazolin.
Anconeal process
removal of
combined medial approach for, 1190, 1191*f*
lateral approach for, 1190
ununited, 1174*t*, 1188–1191
definition for, 1188
diagnosis of, 1189, 1189*b*, 1189*f*
differential diagnosis of, 1189
general considerations and clinically relevant pathophysiology of, 1188–1189
medical management of, 1189
prognosis for, 1191, 1191*b*
surgical treatment of, 1189
anesthesia for, 1190
combined medial approach, for removal of the anconeal process and medial coronoid process, 1190, 1191*f*
complications of, 1191
lag screw fixation for, 1190–1191, 1191*f*
lateral approach, for removal of the anconeal process, 1190, 1190*f*
positioning for, 1190
postoperative care after, 1191
preoperative management of, 1190
surgical anatomy for, 1190
suture materials and special instruments for, 1191
ulnar osteotomy for, 1190
Anconeus muscle, 1064*f*, 1075*f*, 1078*f*
Anemia, with chronic kidney disease, 650–651
anesthetic considerations for, 651
Anesthesia, 125–139
balanced, 125
endobronchial blockers for, 135*b*, 136
endotracheal tubes for, 135–136, 135*b*, 135*t*

Anesthesia *(Continued)*
equipment of, 135–137
fluid therapy and, 139
general considerations of, 125, 125*b*
inhalant, 125, 127*b*
machines, 137
monitoring of, 137–139
body temperature, 139
cardiovascular system, 137–138
respiratory system, 138–139
neuraxial (epidural and spinal), 153–154, 153*t*
contraindications to, 153–154, 154*b*
placement of, 154
volume of agent for, 153–154
regional
intravenous, 152
nerve blocks for
femoral/sciatic, 153
intercostal, 152
RUMM, 152–153
supraglottic devices for, 135*b*, 136, 136*f*
total intravenous, 125
Anesthesia induction area
daily cleaning of, 24–25, 24*b*
description and function of, 19, 19*b*, 20*t*
Anesthesia supply room, 19
Anesthesia time, infections related to, 85, 85*b*
Anesthesiologist, 23
Anesthetics, 125–139
alpha-2 agonists and antagonists, 127*t*–131*t*, 132
antimuscarinics, 125, 127*t*–131*t*
barbiturates, 127*t*–131*t*, 133–134, 134*b*
dissociatives, 127*t*–131*t*, 134–135
general considerations of, 125, 125*b*
inhalants, 127*t*–131*t*, 135
neuroactive steroids, 127*t*–131*t*, 134
nonbarbiturate hypnotics, 134
opioids, 127*t*–131*t*, 132–133, 133*b*
safety checklist, 125, 126*f*, 127*t*–131*t*
tranquilizers, 125–132, 127*t*–131*t*
Anestrus, hormone concentrations during, 720–721
Angiogenesis, in wound healing, 180
Angiography
magnetic resonance, 174–175, 175*f*
for patent ductus arteriosus, 802, 802*b*
Angiosarcoma. *see* Hemangiosarcomas.
Angle of anteversion, 1209
Angle of inclination, 1209
of femur, 1111
Angle of reduction, 1209, 1210*f*
Angle of ventroversion, 1209
Angled thoracic forceps, 796–797, 797*f*
Angular limb deformity(ies). *see* Radial growth deformities.
Anhydrous ammonia, chemical injuries due to, 242
Animal bite wounds, 243–244, 243*f*, 244*b*
Animal sources, of contamination, 1
Anipryl (selegiline), for cognitive dysfunction syndrome, 1445–1447
Ankylosis, 1134
Anorectal abscesses. *see* Perianal fistulae.
Antacids, for gastric ulceration and erosion, 429
Antecurvatum, 1032, 1033*f*
Antepubic urethrostomy, 692, 694*f*
Anterior corneal epithelium, 283*f*
Anterior uveitis, 281
Anteversion, angle of, 1209
Anthelix, 306*f*
Antiandrogens, for benign prostatic hyperplasia, 763–764
Antiarrhythmics
for cardiac disease, 789*b*
for gastric dilatation-volvulus, 423–424, 425*b*
Antibiotic(s), 36
for joint disease, 1139–1140, 1140*t*
for surgical infections, 79–89
aminoglycosides as, 82
bactericidal, 79, 79*b*
bacteriostatic, 79, 79*b*
cephalosporins as, 80, 80*t*
chloramphenicol as, 81, 81*t*
clindamycin as, 81*t*, 82
"drugs of last resort" as, 82–83
erythromycin as, 81–82
failure of, 83
fluoroquinolones as, 82
inappropriate administration of, 79*b*
β–lactam, 79–80, 82*b*
mechanisms of action of, 79–82
destruction of bacterial cells walls as, 79–81
inhibition of DNA synthesis as, 82, 82*b*
inhibition of protein synthesis as, 81–82, 81*b*–82*b*, 87
penicillins as, 80
prophylactic use of, 86–88
considerations for selection and administration of, 87*b*
defined, 79
most likely organisms and, 87, 87*t*
perioperative, 86
postoperative, 88
route of administration of, 87–88
selection and timing of, 87
surgical procedures that warrant, 86, 86*b*
resistance to, 79
multidrug, 82–83
tetracyclines as, 81–82, 81*b*
therapeutic use of, 79, 86–88, 88*b*
existing, 88
for wound healing
systemic, 186
topical, 186–187
Antibiotic-impregnated collagen sponges (CollaRx), 200
Anticonvulsant drugs, for congenital hydrocephalus, 1349
Antidrool cheiloplasty, 251, 253*f*
Antiestrogenic drugs, for benign prostatic hyperplasia, 763–764
Antihypertensives, for cardiac disease, 789*b*
Antiinflammatory drugs
for cervical disc disease, 1378
for cognitive dysfunction syndrome, 1445–1447
for joint disease, 1139, 1139*b*, 1139*f*, 1140*t*
Antimicrobial dressings
other, 197*t*–198*t*, 200
polyhexamethylene biguanide, 197*t*–198*t*, 199–200
Antimicrobial prophylaxis, 36
Antimicrobial roll gauze (Kerlix AMD), for outer layer of bandage, 201
Antimicrobial soaps, for surgical scrub, 44, 46*t*
Antimicrobial-coated sutures, 63–64
Antimicrobials, for wound healing
systemic, 186
topical, 186–187
Antimuscarinics, 125, 127*t*–131*t*
Antioxidants, for portosystemic shunts, 555
Antirobe. *see* Clindamycin.
Antiseizure drugs
for brain surgery, 1339–1340, 1339*t*
for brain tumors, 1360*b*
Antisepsis, 2*b*, 36
Antiseptics
defined, 2*b*
for sterile skin preparation, 38–39, 38*b*
alcohol-based solutions as, 38–39, 38*t*, 39*b*
Antitragus, 306*f*
Antivenin (Crotalidae Polyvalent Immune Fab, Crofab), 245–246
Antral mucosal hypertrophy, chronic
defined, 425
differential diagnosis of, 418
Anus, 482–510
anal sac infection and impaction of, 493–496
anesthetic considerations with, 483
antibiotics for, 483
complications of, 489, 489*b*
definitions for, 482
fecal incontinence of, 507–510
neoplasia of, 489–493
perianal fistulae of, 501–504
postoperative care and assessment after, 488–489
preoperative concerns with, 482–483, 482*b*
special age considerations with, 489
surgical anatomy of, 483–484, 484*b*
surgical techniques for, 484–487
anal sacculectomy, 487, 487*b*
rectal resection, 484–487
suture materials and special instruments for, 488
Anusitis. *see* Perianal fistulae.
AO (Arbeitsgemeinschaft fur Osteosynthesefragen), 1016

Assisted gloving, 47–48, 49*f*
Assisted standing exercises
with elevated front legs, 120–121
as neurologic rehabilitation exercises, 121
as therapeutic exercise, 118
Association for the Study of Internal Fixation (ASIF), 1016
Astrocytoma, intracranial, 1360*f*
Atapryl (selegiline), for cognitive dysfunction syndrome, 1445–1447
Ataxia, 1331–1332, 1332*b*
Atenolol (Tenormin), for cardiac disease, 789*b*
Atipamezole, 144, 148*t*–149*t*
to reverse alpha-2 agonists, 127*t*–131*t*, 132
Atlantoaxial (AA) instability, 1389
complications of, 1394
diagnosis of, 1390–1391, 1391*f*
medical management of, 1391
pathophysiology of, 1389–1390
prognosis for, 1394
surgical technique of, 1392, 1393*f*–1394*f*
surgical treatment of, 1391–1392
anatomic variations and, 1401, 1401*t*
Atlantoaxial (AA) instability *(Continued)*
dorsal fixation methods for, 1392, 1393*f*
Kirschner wires and PMMA in, 1392, 1392*f*
multiple pins and screws in, 1392, 1393*f*
PMMA in, 1392, 1393*f*
positioning for, 1392, 1401
preoperative management of, 1401
reduction of atlantoaxial subluxation in, 1392, 1392*f*
suture materials and special instruments for, 1394
Atlantoaxial (AA) joint capsule, 1368*f*
Atlantoaxial (AA) subluxation, reduction of, 1392, 1392*f*
Atlanto-occipital joint capsule, surgical anatomy of, 1368*f*
Atlanto-occipital overlapping (AOO), 1389
defined, 1389
imaging of, 1390*f*
pathophysiology of, 1389–1390
Atlas, 1366–1367
transverse ligament of, 1368*f*
Atopica. *see* Cyclosporine.
Atracurium besylate (Tracrium)
for cesarean section, 725*t*–726*t*
for fracture repair, 977*t*–978*t*
for inflow occlusion, 793*b*
for liver surgery, 541*t*–542*t*
Atrial septal defect (ASD), 813–815
definitions for, 813
diagnosis of, 813–814, 814*b*
differential diagnosis of, 814
general considerations and clinically relevant pathophysiology of, 813, 813*f*
medical management of, 814
prognosis for, 815
surgical treatment of, 814, 814*f*–815*f*
Atrial standstill, 825
medical management of, 828–829, 828*b*
pathophysiology of, 825, 826*f*–827*f*
Atrioventricular (AV) block
first-degree, 826*f*–827*f*, 827, 828*b*
second-degree (incomplete), 827
third-degree (complete), 826*f*–827*f*, 827
Atrophic nonunion, 1032, 1032*f*
Atropine
for eyelid surgery, 266–268
for large intestinal surgery, 467
for premedication, 125, 127*t*–131*t*
Atropine response test, 827*b*
ATT (ammonia tolerance test), with portosystemic shunt, 554
Attenuation, 170–171
Attire, surgical, 42–43, 43*f*
Attitude, 1328–1331
decerebellate rigidity in, 1330–1331
decerebrate rigidity in, 1330–1331, 1331*f*
defined, 1328–1330
head tilt in, 1328–1330, 1330*f*
head turn in, 1328–1330, 1330*f*
Schiff-Sherrington posture in, 1330, 1331*f*
wide-based stance in, 1330, 1330*f*
Auditory meatus, 305, 305*f*

Auditory ossicles, 305, 305*f*
Auditory tube, 305, 305*f*
Aural cholesteatomas, 316
Aural hematomas, 319–330
  defined, 319
  diagnosis of, 320
    clinical presentation in, 320
    imaging in, 320
    laboratory findings in, 320
    physical examination findings in, 320
  differential diagnosis of, 320
  general considerations and clinically relevant pathophysiology of, 319–320
  medical management of, 320, 320*b*
  postoperative care and assessment after, 322, 322*b*–323*b*, 322*f*–323*f*
  prognosis for, 322–323
  surgical techniques for, 321–322, 321*f*
  surgical treatment of, 320
    anesthesia for, 320
    positioning for, 320
    preoperative management of, 320
    surgical anatomy for, 320
Auricular hematomas. *see* Aural hematomas.
Autoclaving, 58, 58*b*
Autogenous fat grafts
  radial ostectomy and, 1082, 1082*f*
  ulnar ostectomy and, 1081–1082, 1082*f*
Autogenous tissue, for caudate cruciate ligament injury, 1250
Autografts, 232–233
  bone. *see* Bone autografts.
Autoimmune polymyositis, 1462–1463
Autologous fibrin glue (Vivostat), 67
Autologous stem cell, 971
Autolytic débridement, 182
Autoregulation, 1338
AV (atrioventricular) block
  first-degree, 826*f*–827*f*, 827, 828*b*
  second-degree (incomplete), 827
  third-degree (complete), 826*f*–827*f*, 827
Avagard, for surgical scrub, 44–46
Avascular necrosis, of femoral head. *see* Legg-Perthes disease.
Avitene, for hemostasis, 76
Avulsion(s)
  of ear margin. *see* Ear cartilage, traumatic lesions of.
  mesenteric, 512–513, 512*b*
Avulsion fractures, 958*b*, 983–984
  of femoral head, 1111
  metacarpal or metatarsal, 1088*f*, 1090, 1090*b*
  of supraglenoid tuberosity, 1052
  of tibial tuberosity, 1132, 1132*f*
Avulsion wounds, 183
Axial pattern flaps, 222–226, 223*f*
  caudal auricular, 222–223
  caudal superficial epigastric, 224–225, 225*b*, 225*f*
  cranial superficial epigastric, 225
  deep circumflex iliac, 225
  defined, 217, 222
  direct cutaneous vessels used in, 222–223, 223*f*
  genicular, 225
Axial pattern flaps *(Continued)*
  lateral caudal, 226
  lateral thoracic, 224
  omocervical (superficial cervical), 223–224
  reverse saphenous conduit, 225–226, 226*f*
  superficial brachial, 224
  superficial temporal artery, 223
  thoracodorsal, 224, 224*b*, 224*f*
Axial skeleton, 1299
  osteosarcoma of, 1300*t*
Axillary lymph nodes, 631, 632*f*
Axis, 1366–1367
Axonotmesis, 1430, 1430*t*
Azathioprine (Imuran)
  for acquired myasthenia gravis, 953*b*
  for colitis, 478*b*
  for idiopathic immune-mediated polyarthritis, 1151*b*
  for immune-mediated polyarthritis, 1151–1152, 1151*b*
  for noninfectious inflammatory disease, 1455*b*
  for perianal fistula, 503, 503*b*
  for rheumatoid arthritis, 1153*b*
Azithromycin (Zithromax), 81–82, 81*t*
  for Lyme disease, 1150, 1150*b*
  for upper respiratory infection, 838*b*
Azium. *see* Dexamethasone.
Aztreonam, 81
Azulfidine (sulfasalazine), for colitis, 478*b*
Azygos vein, 794–795, 794*f*

B

Babcock tissue forceps, 54, 55*f*
Backhaus towel clamps, 39–40, 39*f*
Backwards walking, as therapeutic exercise, 120
Bacterial arthritis, 1146–1149
  definition for, 1146
  diagnosis of, 1146–1147, 1147*b*, 1147*f*
  differential diagnosis of, 1147
  general considerations and clinically relevant pathophysiology of, 1146
  medical management of, 1139–1140, 1140*t*, 1147–1148, 1148*b*
  prognosis for, 1149
  surgical treatment of, 1148, 1148*b*
Bacterial cell walls, destruction by antibiotics of, 79–81
Bacterial L forms, septic arthritis due to, 1147–1148, 1148*b*
Bactericidal antibiotics, 79, 79*b*
Bacteriostatic antibiotics, 79, 79*b*
Bacteroides spp., pyothorax due to, 948*t*
BAER (brainstem auditory evoked response), 1325
Balance, evaluation of, 1325
Balance boards, as therapeutic exercise, 118, 119*f*
Balance discs, as therapeutic exercise, 118, 119*f*
Balanced anesthesia, 125
Balanced electrolyte solutions, 31
Balfour retractors, 54, 54*f*
Ball work, as therapeutic exercise, 119
Balloon(s), for endoscopy, 162
Balloon catheter-assisted removal, of esophageal foreign bodies, 379, 379*f*
Balloon dilation, for esophageal strictures, 382–383, 382*b*
Balloon valvuloplasty, for pulmonic stenosis, 807
Bandage(s), 194–204. *see also* Wound dressing(s).
  desirable characteristics of, 194, 194*b*
  materials for, 195–201
    contact (primary) layer, 195–200
      factors in selection of, 195, 195*b*
      hydrophilic, 195–196, 195*b*
      types of, 195, 197*t*–198*t*
      wound contraction and, 195, 195*b*
    intermediate (secondary) layer, 200–201
    outer (tertiary) layer, 201
    selection of
      based on purpose, 195, 196*t*
      based on wound characteristics, 195, 197*t*
  types of, 201–203
    absorbent, 201
    postoperative or closed wound, 202
    pressure, 202
    pressure relief, 202–203, 202*f*
    Robert Jones, 201–202
      application of, 982, 982*b*, 982*f*
      for temporary fracture stabilization, 981–982
    spica, 204, 206*f*
    stabilizing, 201–202
    tie-over, 201, 201*f*–202*f*
Bandage débridement, 185
Bandage scissors, 50
Bandaging techniques, 203–204
  for extremities, 203–204, 205*f*–206*f*
  for head, 203, 203*f*
  for paw, 204, 206*f*
  for thorax and abdomen, 203
Barbiturates, 127*t*–131*t*, 133–134, 134*b*
  for brain surgery, 1340
  for liver surgery, 540–542
Bard Biopsy instrument, for liver biopsy, 544
Barden test, 965–966
Barotrauma, 934–935
Barrier, 2*b*
Basal energy requirement (BER), 90
Basilar invagination, pathophysiology of, 1389–1390
Basins, pouring solutions into, 16
Basophils, high, 28*t*
Baytril. *see also* Enrofloxacin.
  for septic arthritis, 1140*t*
BCS (body condition scores), 107, 107*b*, 108*f*–109*f*
  for joint disease, 1137, 1138*f*
Belt-loop gastropexy, 409–410, 413*f*
Benazepril (Lotensin)
  for cardiac disease, 789*b*
  for congestive heart failure, 809*b*
Benign antral muscular hypertrophy. *see* Pyloric stenosis.
Benign esophageal strictures. *see* Esophageal strictures.

Benign prostatic hyperplasia (BPH)
diagnosis of, 763, 763*b*
differential diagnosis of, 763
general considerations and clinically relevant pathophysiology of, 762
glandular or complex, 762
medical management of, 763–764, 764*t*
surgical treatment of, 764
Benzodiazepines, for premedication, 127*t*–131*t*, 131
diazepam as, 127*t*–131*t*, 131
flumazenil as, 127*t*–131*t*, 131
midazolam as, 127*t*–131*t*, 131
zolazepam as, 127*t*–131*t*, 131
Benzopyrones
for chylothorax, 943, 943*b*
for lymphedema, 636, 636*b*
BER (basal energy requirement), 90
Beta amyloid (Aβ), 1444
Betapace (sotalol)
for cardiac disease, 789*b*
for gastric dilatation-volvulus, 423–424, 425*b*
Bethanechol (Urecholine), to improve urination, 701*t*
Bicarbonate therapy
calculation of volumes needed for, 27, 27*b*
for peritonitis, 530–531, 530*b*
Biceps brachii muscle, 1055*f*
Biceps femoris muscle, 1101*f*, 1104*f*, 1112*f*
Biceps femoris muscle biopsy, 1461*f*
Biceps insertion, on ulna, release of, for medial compartment disease, 1185
Biceps reflex, 1334–1335, 1335*f*
Biceps tendon disease, 1169–1172, 1286
definitions for, 1169–1170
diagnosis of, 1170, 1171*f*
differential diagnosis of, 1170
general considerations and clinically relevant pathophysiology of, 1170
medical management of, 1170–1171
prognosis for, 1172
surgical treatment of, 1171–1172, 1172*f*
Bicipital tendon tenodesis, 1169–1171
Bicipital tenosynovitis, 1169–1170
Bicipital tenotomy, 1169–1171
Bier block, 152
Bilateral advancement flaps, 215, 216*f*
Bilateral-biplanar (type III) fixator, 998*f*, 1002
Bilateral-uniplanar (type II) fixator, 998*f*, 1001–1002
Bile acid concentration, with portosystemic shunt, 554
Bile duct, 572*f*, 573
stenting of, 573
Bile duct carcinomas, 566
Bile flow diversion, 574–576, 575*b*–576*b*, 577*f*
Bile peritonitis, 528, 581–584
definition for, 581
diagnosis of, 581, 582*b*
differential diagnosis of, 582–583, 583*b*
general considerations and clinically relevant pathophysiology of, 582, 582*b*
medical management of, 583
Bile peritonitis *(Continued)*
prognosis for, 584
surgical treatment of, 583, 583*b*
Biliary cystadenomas, 566
Biliary system, extrahepatic. *see* Extrahepatic biliary system.
Bilious ascites. *see* Bile peritonitis.
Bilirubin, high, 28*t*
Billroth I procedure, 398, 403, 403*b*, 404*f*
Billroth II procedure, 398, 403, 405*f*
Bioactive dressings, 197*t*–198*t*, 200
Biobrane (silicone membrane and porcine collagen) dressing, 197*t*–198*t*, 200
Biochemical values, age-related differences, 26*b*
Bioclusive dressing, 197*t*–198*t*, 200
BioDres (hydrogel dressing), 197*t*–198*t*, 198–199
Bioglass, for bone grafting, 995
Bioglue, 67
Bioguard (polyurethane film dressing), 197*t*–198*t*, 200
Biologic dressings, 197*t*–198*t*
Biologic tissue grafts, 68
Biological indicator, for sterilization, 10
Biomaterials, 60–78
biologic tissue grafts as, 68
ligating clips as, 67
skin staples as, 67–68
sutures as. *see* Suture(s).
synthetic surgical mesh as, 68
tissue adhesives as, 66–67
Biopsy
bone, 1302–1303
equipment for, 1302, 1303*f*
important considerations for, 1303*b*
limb-sparing procedure and, 1302*b*
of claws, 255–257, 256*f*
colonic, for colitis, 479
CT for, 175, 177*f*
endoscopy for, 161*f*
care after, 166
equipment for, 161, 164–165
of gastrointestinal mucosa, 165
indications for, 159–160
fine needle aspiration
of bone neoplasia, 1301, 1302*b*
of liver, 545
of lung, 893
of lymph node, 633
transrectal, of prostate, 742
of large intestine, 469
liver
indications for, 544*b*
laparoscopic, 545–546, 546*b*
percutaneous, 544–545
blind, 545
false-negative results with, 545*b*
fine-needle aspiration and, 545
sedation for, 545
ultrasound-guided, 545
preoperative concerns for, 540*b*
surgical, 546, 547*f*
tissue core, 544, 544*f*
lung, 893–894
directed keyhole, 894
fine-needle aspiration, 893
intrathoracic, 894
Biopsy *(Continued)*
keyhole, 893
surgical, 894
thoracoscopic, 893–894
for pulmonary neoplasia, 903
lymph node, 633
fine-needle aspiration, 633
incisional, 633, 633*f*
TruCut, 633, 633*b*
of nasal tumors, 878
of oral cavity and oropharynx, 334, 334*b*
pancreatic, 604
laparoscopic, 604
surgical, 604
prostatic, 742
complications of, 745*b*
open, 742
palpation-guided, 742
ultrasound-guided, 742
renal, 654–655, 654*b*–655*b*
laparoscopically-guided, 655
surgical, 655, 655*f*
needle, 655
wedge, 655
ultrasound-guided percutaneous, 654, 655*f*
skin, 212–213
of small intestine, 437–438
splenic, 639–640
aspiration, 639
laparoscopic, 640–641
surgical, 640
testicular, 741–742, 745*b*
transurethral, of bladder and urethral neoplasia, 710
Biopsy channel, of flexible endoscope, 158
Biopsy forceps, endoscopic, 161, 161*f*
Biosol (neomycin)
for perineal, rectal, or colonic surgery, 467–468, 468*b*
for portosystemic shunts, 555, 555*b*
Biosyn (glycomer 631) sutures, 62, 63*t*
Bipedicle advancement flaps, 215, 216*f*
Bipedicle flaps, 218, 221*f*
Bipolar electrosurgery, 77–78
Bisacodyl (Dulcolax), for large intestinal and rectal surgery, 467, 467*b*
Bishop-Harmon forceps, 53*f*
Bite wounds
animal, 243–244, 243*f*, 244*b*
snake, 244–246, 244*b*–245*b*
severity score, 245*b*, 245*t*
treatment of, 245–246
Bivalve cast, 996–997, 997*b*
Black stain, on instruments, 58*t*
Bladder, 678–719
calculi of, 700–705
definitions for, 678
feline idiopathic cystitis of, 717–719
healing of, 696
innervation to, 727*f*
neoplasia of, 707–712
surgical anatomy of, 684, 684*f*–686*f*
surgical technique for, 684–696, 685*f*–686*f*
for cystostomy (prepubic catheterization), 685–686, 687*f*

Bladder *(Continued)*
for cystotomy, 685–687, 685*b*, 687*f*
for urinary diversion, 694–696, 696*f*
surgical treatment of
anesthesia for, 679–684, 680*t*–684*t*
antibiotics for, 684, 684*b*
complications of, 697
postoperative care after, 696–697
preoperative management of, 678–679, 679*b*, 679*f*
special age considerations with, 697–698
suture materials and special instruments for, 696, 696*b*
urinary incontinence of, 712–717
uroabdomen of, 698–700
vascular and nerve supply to, 689*f*
Bladder calculi, 700–705
definitions for, 700
diagnosis of, 702–703
history in, 703
imaging in, 703, 703*b*, 703*f*
laboratory findings in, 703, 703*b*
physical examination in, 703
signalment in, 702–703, 702*b*
differential diagnosis of, 703
general considerations and pathophysiology of, 701, 701*b*–702*b*, 702*f*, 702*t*
medical management of, 703–704, 704*b*, 704*f*
prognosis for, 705
surgical technique for, 705
surgical treatment of, 704–705
anesthesia for, 705
complications of, 705
laparoscopically assisted cystoscopy for, 704
lithotripsy for, 704
positioning for, 705
postoperative care after, 705, 705*b*
preoperative management of, 704–705, 705*b*
stone analysis in, 704*b*
surgical anatomy for, 705
suture materials and special instruments for, 705
Bladder flap reconstruction, of hypoplastic urethra, 716, 716*f*–717*f*
Bladder neoplasia, 707
complications of, 711
definitions for, 707
diagnosis of, 709–710, 709*f*
differential diagnosis of, 710
general considerations and pathophysiology of, 708–709, 709*b*
medical management of, 710, 710*b*
postoperative care after, 711
prognosis for, 711–712
surgical technique for, 711
surgical treatment of, 710–711, 711*f*
suture materials and special instruments for, 711
Bladder rupture
diagnosis of, 698–699, 698*b*, 699*f*
differential diagnosis of, 699
medical management of, 699–700, 700*b*
preoperative management of, 678
Bladder rupture *(Continued)*
prognosis for, 700
surgical treatment of, 700
complications of, 700
postoperative care after, 700, 700*b*, 701*t*
suture materials and special instruments for, 700
uroabdomen due to, 698
Bladder-flap ureteroplasty, 659, 661*f*
Blalock-Taussig shunt, modified, for tetralogy of Fallot, 816, 816*f*
Bleb, pulmonary, 933, 934*f*
Blenderized diets, 90, 91*t*
Blind percutaneous gastrostomy tube placement, 98, 99*f*
Blink reflex, 1325, 1327*f*
Bloat, 419
β-Blockade, 593
Blood clot formation, in wound healing, 179–180
Blood pressure, after cardiac surgery, 797–798
Blood products, 32*t*, 33–34, 34*b*
Blood transfusions
calculation of volumes needed for, 27, 27*b*
whole, 33–34
Blood type, 33–34
Blood urea nitrogen (BUN)
high, 28*t*
low, 28*t*
Blood volume, normal, 31
Bluish black stain, on instruments, 58*t*
Bluish gray stain, on instruments, 58*t*
Blunt point needles, 64, 65*f*
BMPs (bone morphogenic proteins), for bone grafting, 994
Body condition scores (BCS), 107, 107*b*, 108*f*–109*f*
for joint disease, 1137, 1138*f*
Bone
and fracture healing, 974
subchondral, 1141–1142, 1142*f*
Bone allografts
cancellous, 993
cortical, 993
with carpal arthrodesis, 1305, 1308*f*
for cervical spondylomyelopathy, 1385, 1387*f*
defined, 958*b*
Bone autografts
cancellous, 991–993
from distal femur, 993
from ilial wing, 993, 993*f*
from proximal humerus, 992, 992*f*
from proximal tibia, 992
revascularization of, 993, 994*f*
cortical, 993
defined, 958*b*
Bone biopsy, for bone neoplasia, 1302–1303
equipment for, 1302, 1303*f*
important considerations for, 1303*b*
limb-sparing procedure and, 1302*b*
Bone bruise, 171
Bone cutters, 54–55, 56*f*
Bone edema, 171
Bone formation
endochondral, 958*b*, 1025
intramembranous, 958*b*, 1025
Bone grafting, 991–995
bioglass for, 995
bone marrow for, 994
bone morphogenic protein for, 994
cancellous bone allografts for, 993
cancellous bone autografts for, 991–993
from distal femur, 993
from ilial wing, 993, 993*f*
from proximal humerus, 992, 992*f*
from proximal tibia, 992
revascularization of, 993, 994*f*
ceramics for, 995
collagen for, 994
cortical bone allografts for, 993
cortical bone autografts for, 993
demineralized bone matrix for, 994
mesenchymal stem cells for, 995
platelet-rich plasma for, 995
polymer for, 995
properties of materials used for, 991, 992*t*
Bone healing, 1025–1030, 1025*b*
direct, 1026–1027, 1027*f*–1028*f*
indirect, 1025–1026, 1025*f*–1027*f*
inflammatory phase of, 1025
intramembranous, 1027–1028, 1028*f*–1029*f*
physeal, 1028, 1031*f*
trabecular, 1028, 1030*f*
Bone lengthening
circular external fixator for, 1005–1006, 1006*b*
unifocal and bifocal, 1005
Bone marrow, for bone grafting, 994
Bone marrow concentrate, 971
Bone marrow derived stem cells, 968, 971
Bone marrow lesion, 171
Bone marrow transplantation, 970
Bone morphogenic proteins (BMPs), for bone grafting, 994
Bone neoplasia, 1299–1308
bone biopsy for, 1302–1303
equipment for, 1302, 1303*f*
important considerations for, 1303*b*
limb-sparing procedure and, 1302*b*
with concurrent orthopedic or neurologic disease, 1302*b*
definitions for, 1299
diagnosis of, 1301–1302
clinical presentation in, 1301
imaging in, 1301, 1301*b*, 1301*f*
laboratory findings in, 1301–1302
physical examination findings in, 1301, 1301*b*
differential diagnosis of, 1302
general considerations and clinically relevant pathophysiology of, 1299–1300, 1299*b*, 1300*t*
limb-sparing techniques for, 1305
bone biopsy and, 1302*b*
cortical allograft with carpal arthrodesis, 1305, 1308*f*
medical management of, 1302
metastatic, 1299
postoperative care and assessment after, 1306–1307, 1307*b*

Bone neoplasia *(Continued)*
primary, 1299
prognosis for, 1307–1308
staging of, 1301–1302
surgical technique for, 1302–1305
acetabulectomy for, 1305
amputation for, 1303–1305
coxofemoral disarticulation, 1303–1304, 1306*f*
forequarter, 1303, 1304*f*–1305*f*
hemipelvectomy as, 1303, 1303*f*
midfemoral, 1305, 1307*f*
surgical treatment of, 1302
anesthesia for, 1302
positioning for, 1302
preoperative management of, 1302, 1302*b*
surgical anatomy for, 1302
suture materials and special instruments for, 1305–1306
Bone plates, 1016–1023. *see also* Plate and screw fixation.
for acetabular fracture, 1100, 1102*f*
application of, 1021–1023, 1021*b*
bridging, 1019
application of, 1022, 1022*f*
use of locking plate as, 1022–1023, 1023*b*
buttress, 1019, 1019*f*
application of, 1022
canine acetabular, 1019
compression
application of, 1021–1022, 1021*f*
dynamic, 1018*f*
application of, 1021*f*
limited-contact, 1018, 1018*f*
locking, 1017–1018, 1017*f*
configuration of, 1018–1019
for femoral bicondylar fracture, 1113, 1113*f*
hole configuration of, 1018
for humeral diaphyseal fractures, 1057, 1057*f*–1058*f*
for iliac fractures, 1097–1098, 1097*f*
indications and biomechanical principles of, 1016–1017
length of, 1018
locking, 1016–1018
application of, 1022–1023
for mandibular and maxillary fractures, 1040, 1041*f*
neutralization, 1019, 1019*f*
application of, 1022
for radial diaphyseal fractures, 1071, 1071*f*
reconstruction, 1019
for tibial diaphyseal fractures, 1124, 1124*b*, 1126*f*
types of, 1018, 1018*f*
Bone scintigraphy, of fragmented coronoid process, 1176
Bone screws, 1016–1023. *see also* Plate and screw fixation.
application of, 1019–1021
cancellous, 1017, 1017*f*
cortical, 1017, 1017*f*
indications and biomechanical principles of, 1016–1017
Bone screws *(Continued)*
instrumentation for, 1017
lag, 1017
application of, 1019–1020, 1020*b*, 1020*f*
locking, 1016–1017
application of, 1021
plate, 1017
application of, 1021, 1021*f*
position, 1017
application of, 1020–1021
postoperative care for, 1023
self-tapping, 1017
thread height of, 1017
Bone transport, circular external fixator for, 1006, 1006*f*
Bone union
delayed, 958*b*, 1031
direct, 958*b*
Bone wax, for hemostasis, 75
Bone-holding forceps, 54–55, 55*f*
Border cells, 1328–1330, 1331*f*
Borrelia burgdorferi, Lyme arthropathy due to, 1149, 1150*b*
BOSU ball, as therapeutic exercise, 118, 119*f*
Bougie(s), for endoscopy, 162
Bougienage, for esophageal strictures, 382, 382*b*
Bow tie technique, for circular skin defects, 214, 214*f*
Bowel plication, to prevent recurrence of intussusception, 448, 448*b*, 448*f*
Bowel preparation, for large intestinal and rectal surgery, 467, 467*b*
BPH. *see* Benign prostatic hyperplasia.
Brachialis muscle, surgical anatomy of, 1055*f*
Brachiocephalicus muscle, surgical anatomy of, 1055*f*, 1063*f*, 1066*f*
Brachycephalic airway syndrome. *see* Brachycephalic syndrome.
Brachycephalic obstructive airway syndrome. *see* Brachycephalic syndrome.
Brachycephalic syndrome, 849–856
anesthetic considerations with, 836*t*–837*t*
breeds commonly affected with, 849*b*
clinical presentation of, 851–852
definitions for, 849
diagnosis of, 851–853
diagnostic imaging for, 852–853
differential diagnosis of, 853
general considerations and clinically relevant pathophysiology of, 849–851
laboratory findings in, 853
medical management of, 853
physical examination findings in, 852
prognosis for, 856
surgical treatment of, 853–854
anesthesia for, 853–854
complications of, 856
elongated soft palate resection (staphylectomy) for, 854–855, 855*f*
everted laryngeal saccules resection for, 855, 856*f*
Brachycephalic syndrome *(Continued)*
laser-assisted turbinetomy for, 855
positioning for, 854, 854*f*
postoperative care and assessment after, 856
preoperative management of, 853
stenotic nares resection (rhinoplasty) for, 854, 855*f*
surgical anatomy for, 854
upper airway abnormalities associated with, 850*b*
Brachycephalic trunk, 794–795
Bradycardia, 825–831
definitions for, 825
diagnosis of, 827–828, 827*b*
differential diagnosis of, 828
general considerations and clinically relevant pathophysiology of, 825–827, 826*f*–827*f*
medical management of, 828–829, 828*b*–829*b*
prognosis for, 831
sinus, 825
surgical treatment of, 829
anesthesia for, 829, 829*b*
positioning for, 829
postoperative care and assessment after, 830–831
preoperative management of, 829
surgical technique for, 829, 829*b*, 830*f*–831*f*
suture materials and special instruments for, 829–830
Brain
healing of, 1344–1345
ischemic/vascular disease of, 1448–1453
definitions for, 1448
diagnosis of, 1448–1451, 1450*t*, 1451*f*–1452*f*
differential diagnosis of, 1451, 1452*b*
general considerations and clinically relevant pathophysiology of, 1448, 1448*f*
medical management of, 1451
prognosis for, 1452–1453
surgical treatment of, 1451
major anatomic subdivisions of, 1323, 1324*f*
noninfectious inflammatory disease of, 1453–1455
definitions for, 1453
diagnosis of, 1453–1454, 1454*f*
differential diagnosis of, 1454
general considerations and clinically relevant pathophysiology, 1453
medical management of, 1454–1455, 1455*b*
prognosis for, 1455
surgical treatment of, 1455
nonsurgical disorders of, 1444–1459
cognitive dysfunction syndrome as, 1444–1447
ischemic/vascular disease as, 1448–1453
noninfectious inflammatory disease as, 1453–1455

Brain infarcts
  cryptogenic, 1448
  definitions for, 1448
  general considerations and clinically relevant pathophysiology of, 1448
  hemorrhagic, 1448, 1450, 1450*t*, 1451*f*
  lacunar, 1448
  multifocal, 1448
  nonhemorrhagic, 1448–1450, 1450*t*, 1451*f*
  territorial, 1448
Brain injury, traumatic, 1362–1364
  definition for, 1362
  diagnosis of, 1363, 1363*f*
  differential diagnosis of, 1363
  general considerations and clinically relevant pathophysiology of, 1362–1363, 1362*f*
  medical management of, 1363
  postoperative care and assessment after, 1364
  primary, 1362
  prognosis for, 1364
  secondary, 1362
  surgical technique for, 1364
  surgical treatment of, 1363–1364
  suture materials and special instruments for, 1364
Brain surgery, 1338–1364
  anesthetic considerations for, 1340–1342, 1341*t*–1342*t*
  for brain tumors, 1358–1362
  for Chiari-like malformation, 1353–1358
  complications of, 1346
  for congenital hydrocephalus, 1347–1350
  definitions for, 1338
  general considerations for, 1338–1342
  healing after, 1344–1345
  for intracranial arachnoid cyst, 1350–1353
  intracranial pressure *vs*. volume curve in, 1338, 1339*f*
  postoperative care and assessment after, 1346
  preoperative management of, 1338–1340
  rostrotentorial (lateral) craniotomy as, 1343, 1345*f*
  special age considerations for, 1346
  standard surgical approaches for, 1342–1344, 1343*f*–1344*f*
  suboccipital craniotomy (foramen magnum decompression) as, 1344, 1347*f*
  suture materials and special instruments for, 1345–1346
  transfrontal craniotomy as, 1344, 1346*f*
  for traumatic brain injury, 1362–1364
Brain tumors, 1358–1362
  complications for, 1362
  definitions for, 1358
  diagnosis of, 1358–1359, 1359*f*–1360*f*
  differential diagnosis of, 1359
  general considerations and clinically relevant pathophysiology of, 1358
  medical management of, 1359–1360, 1360*b*
  physical examination findings in, 1359, 1359*b*
Brain tumors *(Continued)*
  postoperative care and assessment for, 1361
  prognosis of, 1361
  surgical technique of, 1360–1361
  surgical treatment of, 1360
  suture materials and special instruments for, 1361
Brainstem auditory evoked response (BAER), 1318, 1318*f*, 1325
Branchial cysts, thymic, 951–954
  clinical presentation of, 951, 951*b*
  definitions for, 951
  diagnosis of, 951–952
  diagnostic imaging of, 952
  differential diagnosis of, 952–953, 953*b*
  general considerations and clinically relevant pathophysiology, 951
  history of, 952
  laboratory findings in, 952
  medical management of, 953, 953*b*
  physical examination findings in, 952
  postoperative care and assessment after, 954
  prognosis for, 954
  proposed staging scheme for, 951*t*
  surgical technique of, 953–954, 954*b*
  surgical treatment of, 953
  suture materials and special instruments for, 954
Braunamid (polymerized caprolactam) sutures, 63*t*
Breaking strength, of sutures, 61*b*
Breathing, abdominal, 1365
Brethine (terbutaline), for aspiration pneumonia, 367*b*
Brevibloc (esmolol)
  for cardiac disease, 789*b*
  for pheochromocytoma, 594–596, 595*t*–596*t*
Bricanyl (terbutaline), for aspiration pneumonia, 367*b*
Bridging osteosynthesis, 986
Bridging plates
  application of, 1022, 1022*f*
  defined, 958*b*, 1019
  use of locking plate as, 1022–1023, 1023*b*
Broad ligament, 725–726, 726*b*
Broken back. *see* Lumbosacral trauma.
Bromocriptine (Parlodel), for pregnancy prevention or termination, 729*b*
Bronchogenic cyst, 901*f*
Bronchoscopy, 158, 159*b*
  for lung lobe torsion, 906, 906*b*, 906*f*
  for tracheal collapse, 869–870
Brown and Sharpe wire gauge sutures, size of, 61*t*
Brown stain, on instruments, 58*t*
Brown-Adson forceps, 52–53, 53*f*
Brucella canis, diskospondylitis due to, 1456–1457
Brush
  for endoscopic cytology, 161
  instrument, 58
  for surgical scrub, 44
Brushless surgical scrub solutions, 44–46, 45*f*
Buccal mucosal flap, with partial maxillectomy, 336, 336*f*
Bucket handle tears, 1243–1244
Bulbar conjunctiva, 281–282
Bulbospongiosus muscle, 727
Bulbourethral gland, 726–727
Bulla(e), pulmonary, 933, 934*f*
Bulla osteotomy
  lateral, 309–310, 312*f*
  ventral, 310, 313*f*
BUN (blood urea nitrogen)
  high, 28*t*
  low, 28*t*
Bunnell suture, 71, 71*f*
Buoyancy, of water, 122–123
Buphthalmos, definition for, 291, 296
Bupivacaine, 148*t*–149*t*, 150
  for thoracostomy tube placement, 918*b*
Buprenorphine, 127*t*–131*t*, 133, 148*t*–149*t*, 151
  for orthopedic surgery, 967
  for severe dyspnea, 834*b*
Buried sutures, 74, 76*f*, 190
Burns, 183, 237–241
  bacterial growth in, 238
  bandage contact layer, 240*t*
  causes of, 237, 237*f*
  chemical, 241–242, 241*f*
  classification of
    deep partial-thickness (second-degree), 237
    fourth-degree, 238
    full-thickness (third-degree), 238, 238*f*
    superficial (first-degree), 237
  due to radiation therapy, 243*b*
    treatment of, 242–243, 242*f*
  electrical, 240–241
  frostbite as, 241
  size of area of, 238–239, 239*t*
  systemic effects of, 239
  treatment of, 238–239
  wound management for, 239–240, 240*f*
Bürow's triangle, backcut or excision of, for triangular skin defects, 215, 215*f*
Bursitis, olecranon, 247–248, 247*f*
  treatment of, 247–248, 248*b*
Butorphanol tartrate (Torbutrol, Torbugesic), 127*t*–131*t*, 148*t*–149*t*
  for insulinomas, 610
  for severe dyspnea, 834*b*
  for tracheal collapse, 871*b*
Butterfly fragment, fractures with, 983–984
  direct reduction of, 989–990, 991*f*
Butterfly needle, for thoracentesis, 920–921, 921*f*
Butterfly vertebra, 1415
Buttress plates, 1019, 1019*f*
  application of, 1022

C

Cabergoline (Dostinex, Galastop)
  for pregnancy prevention or termination, 729*b*
  for pyometra, 757*b*
Cable ties, 62*b*
Calcaneal fractures
  pathophysiology of, 1084
  surgical treatment of, 1085
  transverse, 1085, 1085*f*

Calcaneocentral ligament, surgical anatomy of, 1268, 1269*f*
Calcaneus, 1085–1086
Calcification, of external auditory canal, 314, 314*f*
Calcified cartilage, zone of, 1141–1142, 1142*f*
Calcitonin, 616
Calcitriol, for hypocalcemia after thyroidectomy, 624*b*
Calcium
  high, 28*t*
  low, 28*t*
  serum, 625, 625*t*
Calcium alginate dressings (Curasorb, Sorbalgon), 197*t*–198*t*, 199
Calcium gluconate
  for hyperkalemia, 679*b*, 828*b*
  for hypocalcemia after thyroidectomy, 624
Calcium lactate, for hypocalcemia after thyroidectomy, 624*b*
Calcium oxalate uroliths, 670, 701
  signalment of, 702, 702*b*
  treatment and prevention of, 702*t*
Calculi
  bladder and urethral, 700–705
    definitions for, 700
    diagnosis of, 702–703
      history in, 703
      imaging in, 703, 703*b*, 703*f*
      laboratory findings in, 703, 703*b*
      physical examination in, 703
      signalment in, 702–703, 702*b*
    differential diagnosis of, 703
    general considerations and pathophysiology of, 701, 701*b*–702*b*, 702*f*, 702*t*
    medical management of, 703–704, 704*b*, 704*f*
    prognosis for, 705
    surgical technique for, 705
    surgical treatment of, 704–705
      anesthesia for, 705
      complications of, 705
      laparoscopically assisted cystoscopy for, 704
      lithotripsy for, 704
      positioning for, 705
      postoperative care after, 705, 705*b*
      preoperative management of, 704–705, 705*b*
      stone analysis in, 704*b*
      surgical anatomy for, 705
      suture materials and special instruments for, 705
  renal and ureteral, 669–673
    complications of, 672
    definitions for, 669
    diagnosis of, 670–671, 670*b*, 671*f*
    differential diagnosis of, 671
    general considerations and pathophysiology of, 669–670, 670*f*
    medical management of, 671
    postoperative care and assessment for, 672
    prognosis for, 672
    special age considerations with, 672
Calculi *(Continued)*
    surgical technique for, 672, 672*b*
    surgical treatment of, 671–672, 672*b*
    suture materials and special instruments for, 672
Callus, in indirect bone healing, 1025, 1026*f*
Camera(s), for arthroscopy, 167
Camera portal, 158
Cancellous bone allografts, 993
Cancellous bone autografts, 991–993
  from distal femur, 993
  from ilial wing, 993, 993*f*
  from proximal humerus, 992, 992*f*
  from proximal tibia, 992
  revascularization of, 993, 994*f*
Cancellous screws, 1017, 1017*f*
  for caudal cervical spondylomyelopathy, 1385, 1385*f*
Canine acetabular plate, 1019
Canine a/d, 91*t*
Canine albumin, 28*t*
Canine elbow dysplasia, 1174
  and breeding, 1174*b*
  categorizations and surgical options for, 1174*t*
  considerations for treatment of, 1174*b*
  due to incomplete ossification of the humeral condyle, 1174*t*
  due to medial compartment disease, 1174*t*
  due to medial coronoid disease and fragmented coronoid process, 1174–1180, 1174*t*
  due to osteochondritis dissecans, 1174*t*
  due to radial-ulnar incongruence, 1174*t*
  due to ununited anconeal process, 1174*t*
Canine i/d, 91*t*
Canine idiopathic polyarthritis, 1151, 1151*b*
Canine k/d, 91*t*
Canine scurvy, 1296–1297, 1296*b*–1297*b*, 1297*f*
Canine teeth, 1037*f*
Cannulas
  for arthroscopy, 158
  for rigid endoscopy, 158
Cap(s), for surgical team, 42, 43*f*
Capillarity, of sutures, 60, 61*b*
Capillary(ies), in wound healing, 180
Capillary loop system, 179
Capillary refill time, normal, 917*b*
Capital physeal fractures
  diagnosis of, 1114–1115, 1115*b*
  differential diagnosis of, 1115
  general considerations and pathophysiology of, 1114, 1114*f*
  medical management of, 1115
  prognosis for, 1118, 1119*f*
  surgical treatment of, 1115
    anesthesia for, 1115
    complications of, 1118
    lag screw for, 1117, 1117*f*
    positioning for, 1115
    postoperative care and assessment after, 1118, 1118*f*
    preoperative management of, 1115
    surgical anatomy for, 1115
    surgical technique for, 1115–1118
Capital physeal fractures *(Continued)*
    suture materials and special instruments for, 1118
    triangulated Kirschner wires for, 1116–1117, 1117*f*
Caprosyn (polyglytone 6211) sutures, 62, 63*t*
Capsulectomy, subtotal prostatectomy with, 743
Carafate. *see* Sucralfate.
Carbapenems, 80–81
  as drugs of last resort, 82–83
Carbex (selegiline), for cognitive dysfunction syndrome, 1445–1447
Carbimazole, for feline hyperthyroidism, 619–620, 620*b*
Carbon dioxide (CO_2)
  high total, 28*t*
  low total, 28*t*
Carbon dioxide (CO_2) laser, for hemostasis, 78
Carboxypenicillin, 80
Carcinoids, hepatic, 566
Carcinoma(s), 627
  adrenal
    defined, 590
    general considerations and clinically relevant pathophysiology of, 597
  aortic body, 823
  exocrine pancreatic, 613–615
    defined, 613
    diagnosis of, 614, 614*b*
    differential diagnosis of, 614
    general considerations and clinically relevant pathophysiology of, 614, 614*b*
    medical management of, 614
    prognosis for, 615
    surgical treatment of, 614, 615*f*
  prostatic, 771
Cardiac angiosarcoma, 823
Cardiac arrhythmias, in thoracic wall trauma, 898
Cardiac disease
  advanced imaging modalities for, 175
  drugs used for, 788, 789*b*
Cardiac hemangiosarcoma, 823
  diagnosis of, 823–824, 824*f*
  pathophysiology of, 823
  surgical treatment of, 824
Cardiac neoplasia, 823–825
  definitions for, 823
  diagnosis of, 823–824, 824*f*
  differential diagnosis of, 824
  general considerations and clinically relevant pathophysiology of, 823
  medical management of, 824
  prognosis for, 825
  surgical treatment of, 824, 825*f*
Cardiac notch, 794, 889
Cardiac pacemaker implantation, for bradycardia
  surgical treatment of, 829
    anesthesia for, 829, 829*b*
    electrode placement in, 829, 831*f*
    midline celiotomy in, 829
    positioning for, 829

Cardiac pacemaker implantation, for bradycardia *(Continued)*
postoperative care and assessment after, 830–831
preoperative management of, 829
suture materials and special instruments for, 829–830, 831*f*
technique for, 829, 829*b*
Cardiac surgery, 788–832
anesthesia for, 788–794, 790*t*–793*t*, 793*b*
antibiotics with, 794, 794*b*
for aortic stenosis, 807–810
for atrial septal defect, 813–815
for bradycardia, 825–831
for cardiac neoplasia, 823–825
closed, 788
complications of, 798
definitions for, 788
healing after, 796
for mitral regurgitation, 798–801
open, 788
for patent ductus arteriosus, 801–805
for pericardial effusion and pericardial constriction, 817–823
postoperative care and assessment after, 797–798
preoperative management of, 788, 789*b*
for pulmonic stenosis, 805–807
special age considerations for, 798, 798*b*
surgical anatomy for, 794–795, 794*f*
surgical technique for, 795–796
for cardiopulmonary bypass, 795–796
inflow occlusion as, 795, 795*f*–796*f*
suture materials and special instruments for, 796–797, 796*f*
for tetralogy of Fallot, 815–817
for ventricular septal defect, 811–813
Cardiac tamponade
cardiovascular parameters for, 790*t*
defined, 817
Cardiopulmonary bypass, 788
surgical technique for, 795–796
Cardiovascular parameters, for mitral regurgitation, subaortic stenosis, and cardiac tamponade, 790*t*
Cardiovascular structures, healing of, 796
Cardiovascular surgery. *see* Cardiac surgery.
Cardizem (diltiazem), for cardiac disease, 789*b*
Carotid artery ligation, temporary, 334, 334*b*
Carotid sheath, 1369*f*
Carpal arthrodesis
cortical allograft with, 1305, 1308*f*
pan-, 1205, 1205*f*
defined, 1202
with external fixator, 1205
partial, 1205, 1205*b*, 1206*f*
with cross pins and a lag screw, 1206
defined, 1202
with intramedullary pins, 1205–1206
Carpal bones, approach to, 1204–1205, 1205*f*
Carpal collateral ligament, approach to, 1207, 1208*f*
Carpal fractures, 1084–1087
definitions for, 1084
diagnosis of, 1084
Carpal fractures *(Continued)*
differential diagnosis of, 1085
general considerations and pathophysiology of, 1084
medical management of, 1085
prognosis for, 1087
radial, 1084
stabilization of, 1086
surgical anatomy of, 1085–1086
surgical treatment of, 1085–1086, 1085*f*
anesthesia for, 1085
complications of, 1087
positioning for, 1086
postoperative care and assessment after, 1086–1087
preoperative management of, 1085
surgical anatomy for, 1085–1086
surgical techniques for, 1086
suture materials and special instruments for, 1086
Carpal hyperextension, 1202
categories of, 1202
definitions for, 1202
diagnosis of, 1202–1203
clinical presentation in, 1202–1203
imaging in, 1203, 1204*f*
laboratory findings in, 1203
physical examination in, 1203, 1203*f*
differential diagnosis of, 1203
general considerations and clinically relevant pathophysiology of, 1202
medical management for, 1203
prognosis for, 1206
surgical treatment for, 1204
anesthesia for, 1204
approach to carpal bones in, 1204–1205, 1205*f*
complications of, 1206
pancarpal arthrodesis for, 1205, 1205*f*
with external fixator, 1205
partial carpal arthrodesis for, 1205, 1205*b*, 1206*f*
with cross pins and a lag screw, 1206
with intramedullary pins, 1205–1206
positioning for, 1204
postoperative care after, 1206
preoperative management of, 1204
surgical anatomy for, 1204
suture materials and special instruments for, 1206
Carpal joint disease, 1202–1209
carpal laxity syndrome as, 1208–1209
carpal luxation or subluxation as, 1202–1206
resulting from collateral ligament injury, 1206–1208
Carpal joint orientation angle, in frontal plane, 1081
Carpal laxity syndrome, 1208–1209, 1208*f*
Carpal luxation, 1202–1206
definitions for, 1202
diagnosis of, 1202–1203
clinical presentation in, 1202–1203
imaging in, 1203, 1204*f*
laboratory findings in, 1203
physical examination in, 1203, 1203*f*
Carpal luxation *(Continued)*
differential diagnosis of, 1203
general considerations and clinically relevant pathophysiology of, 1202
medical management for, 1203
prognosis for, 1206
surgical treatment of, 1204
anesthesia for, 1204
approach to carpal bones in, 1204–1205, 1205*f*
complications of, 1206
pancarpal arthrodesis for, 1205, 1205*f*
with external fixator, 1205
partial carpal arthrodesis for, 1205, 1205*b*, 1206*f*
with cross pins and a lag screw, 1206
with intramedullary pins, 1205–1206
positioning for, 1204
postoperative care after, 1206
preoperative management of, 1204
surgical anatomy for, 1204
suture materials and special instruments for, 1206
Carpal pad transfer, 263–265, 264*f*
Carpal subluxation, 1202–1206
definitions for, 1202
diagnosis of, 1202–1203
clinical presentation in, 1202–1203
imaging in, 1203, 1204*f*
laboratory findings in, 1203
physical examination in, 1203, 1203*f*
differential diagnosis of, 1203
due to collateral ligament injury, 1206–1208
definitions for, 1206
diagnosis of, 1206–1207
clinical presentation in, 1206
imaging for, 1207, 1207*f*
laboratory findings in, 1207
physical examination in, 1206
differential diagnosis of, 1207
general considerations and clinically relevant pathophysiology of, 1206
medical management for, 1207
prognosis for, 1208
surgical treatment for, 1207, 1208*f*
general considerations and clinically relevant pathophysiology of, 1202
medical management for, 1203
prognosis for, 1206
surgical treatment for, 1204
anesthesia for, 1204
approach to carpal bones in, 1204–1205, 1205*f*
complications of, 1206
pancarpal arthrodesis for, 1205, 1205*f*
with external fixator, 1205
partial carpal arthrodesis for, 1205, 1205*b*, 1206*f*
with cross pins and a lag screw, 1206
with intramedullary pins, 1205–1206
positioning for, 1204
postoperative care after, 1206
preoperative management of, 1204

Carpal subluxation *(Continued)*
surgical anatomy for, 1204
suture materials and special instruments for, 1206
Carprofen (Rimadyl), 148*t*–149*t*, 150
for cognitive dysfunction syndrome, 1445–1447
Carpus
arthroscopy of, 166*b*
orthopedic examination of, 962
surgical anatomy of, 1085–1086
synovial fluid collection from, 1136*f*
Carravet (hydrogel dressing), 197*t*–198*t*, 198–199
Cartilage
articular
category, 1141–1142, 1142*f*
functions of, 1142
healing of, 1142–1143, 1143*f*
and loss of joint stability, 1141
surgical anatomy of, 1141–1142, 1141*f*–1142*f*
hyaline, 1141
response of, to treatment, 1142–1143
Cartilage defects, healing of, 1142–1143, 1143*f*
Cartilage repair, stem cells for, 973–974
Cartilaginous joints, 1134
Cast(s), 995–997
application of, 996–997, 996*b*–997*b*, 996*f*
bivalve, 996–997, 997*b*
indications and biomechanical principles of, 995–996, 996*b*
postoperative care for, 997, 997*b*, 997*t*
for radial and ulnar diaphyseal fractures, 1069, 1069*b*, 1070*f*
removal of, 1028
for tibial diaphyseal fractures, 1122, 1123*f*
Cast padding
application of, 996–997, 996*f*
for intermediate layer of bandage, 200–201
Castration
canine, 732–734
perineal, 734
prescrotal
closed, 734
open, 732–733, 733*f*
scrotal ablation, 734
complications after, 745, 745*b*
cryptorchid, 734, 735*b*, 736*f*
defined, 720
feline, 734, 735*f*–736*f*
Castroviejo needle holder, 51*f*–52*f*, 52
Catgut sutures, 61, 63*t*
Catheterization, prepubic, 678, 685–686, 687*f*
Cauda equina
defined, 1427
healing of, 1430, 1430*t*
surgical anatomy of, 1428, 1428*f*–1429*f*
Cauda equina surgery, 1427–1443
anesthesia for, 1428
antibiotics for, 1428
complications of, 1430–1431
definitions for, 1427
Cauda equina surgery *(Continued)*
for degenerative lumbosacral stenosis, 1431–1434
general considerations for, 1427–1428
healing after, 1430, 1430*t*
for neoplasia, 1434–1437
postoperative care and assessment after, 1430
preoperative management of, 1428
special age considerations for, 1431
surgical anatomy for, 1428, 1428*f*–1429*f*
surgical technique for, 1428–1430, 1429*f*
for dorsal laminectomy, 1429–1430, 1429*f*
for facetectomy and foraminotomy, 1430
positioning for, 1428, 1429*f*
suture materials and special instruments for, 1430
for trauma, 1437–1442
Caudal auricular artery, 223*f*
Caudal auricular axial pattern flap, 222–223
Caudal cruciate ligament, 1234*f*
Caudal cruciate ligament injury, 1248–1250
definition for, 1248
diagnosis of, 1248–1249, 1248*b*
differential diagnosis of, 1249
general considerations and clinically relevant pathophysiology of, 1248
medical management for, 1249
surgical treatment for, 1249
anesthesia for, 1249
entrapment (tenodesis) of popliteal tendon for, 1250
exploratory arthrotomy for, 1249
positioning for, 1249
postoperative care after, 1250
surgical anatomy for, 1249
suture materials and special instruments for, 1250
suture stabilization for, 1249, 1249*f*
use of autogenous tissue in, 1250
Caudal laryngeal nerve, 839
Caudal lumbar fractures. *see* Lumbosacral trauma.
Caudal pancreaticoduodenal arteries, 603, 604*f*
Caudal sartorius muscle, 1234*f*
Caudal sartorius muscle flap, 230, 230*f*
Caudal superficial epigastric artery, 223*f*
Caudal superficial epigastric artery and vein, 524*f*
Caudal superficial epigastric axial pattern flap, 224–225, 225*b*, 225*f*
Caudal thyroid artery, 616–617
Caudal thyroid vein, 616*f*
Caudal vena cava, 543*f*
Caudal vesical artery, 689*f*
Caudate liver lobe
caudate process of, 543*f*
complete lobectomy of, 549
papillary process of, 543*f*
Caudectomy, 253–255
in adults, 254–255
complete, 255, 256*f*
partial, 255, 255*f*
cosmetic, 253–254
defined, 253–254
therapeutic, 253–254
Cavaletti course, as therapeutic exercise, 118–119, 119*f*
Cavi-Care (silicone foam dressings), 197*t*–198*t*
Cavilon No Sting Barrier Film (skin protectant films), 197*t*–198*t*
Cavitary hepatic lesions, 563–566
definitions for, 563
diagnosis of, 564, 564*b*, 564*f*
differential diagnosis of, 564
general considerations and clinically relevant pathophysiology of, 563–564
medical management of, 564–565, 565*b*
prognosis for, 565–566
surgical treatment for, 565
postoperative care and assessment after, 565
suture materials and special instruments for, 565
technique for, 565
CCL. *see* Cranial cruciate ligament.
CDS. *see* Cognitive dysfunction syndrome.
Cecum, surgical anatomy of, 468
Cefadroxil (Cefa-tabs), 80*t*
for cauda equina surgery, 1428
Cefazolin (Ancef, Kefzol), 80*t*
for brain surgery, 1340
for cardiac surgery, 794*b*
for cauda equina surgery, 1428
for hepatic abscess, 565*b*
for joint surgery, 1140
for pyometra, 757*b*
for renal surgery, 653*b*
for reproductive disorders, 726*b*
for surgical infection prophylaxis, 87, 87*b*
for thoracolumbar spine surgery, 1404
for tracheal collapse, 871*b*
for upper respiratory infection, 838*b*
for wound healing, 187
Cefepime (Maxipime), 80*t*
Cefixime (Suprax), 80*t*
Cefmetazole (Zefazone), for perineal, rectal, or colonic surgery, 467–468, 468*b*
Cefoperazone (Cefobid), 80*t*
Cefotan (cefotetan), for perineal, rectal, or colonic surgery, 467–468, 468*b*
Cefotaxime (Claforan), 80*t*
Cefotetan (Cefotan), 80*t*
for perineal, rectal, or colonic surgery, 467–468, 468*b*
Cefovecin (Convenia), 80*t*
Cefoxitin (Mefoxin), 80, 80*t*
for cardiac surgery, 794*b*
for hepatic abscess, 565*b*
for perineal, rectal, or colonic surgery, 467–468, 468*b*
for peritonitis, 531, 531*b*
for pyometra, 757*b*
for reproductive disorders, 726*b*
Cefpodoxime (Proxetil), 80*t*
Cefquinome (Cobactan), 80*t*
Ceftazidime (Fortaz), 80*t*
Ceftiofur (Naxcel), 80*t*
Ceftobiprole, as drugs of last resort, 82–83
Ceftriaxone (Rocephin), 80*t*
for lyme disease, 1150*b*

Cefuroxime (Biociclin), 80*t*
Ceiling, of operating room, 21
Celiac artery, 604*f*
Celiography, positive contrast, 927
Celiotomy
  defined, 512
  indication for, 512
  paracostal, 517
    abdominal wall closure and, 518
  ventral midline
    in cats and female dogs, 516, 516*f*
    in male dogs, 516–517, 516*f*
β-cell tumors. *see* Insulinomas.
Cell-based therapies, 970
CellCept, for acquired myasthenia gravis, 953*b*
Cellophane banding, of extrahepatic shunts, 558
Cement, chemical injuries due to, 242
CE-MRA (contrast-enhanced magnetic resonance angiography), 174–175, 175*f*
Center of rotation of angulation, of deformity, 1081
Central cord syndrome, 1365
Central parenteral nutrition (CPN), 90
Central sensitization, 142–143, 143*b*
Cephalexin (Keflex), 80*t*
  for renal surgery, 653*b*
  for septic arthritis, 1140*t*
Cephalic vein, 1055*f*
Cephalosporins, 80, 80*t*
CEPSSs. *see* Congenital extrahepatic portosystemic shunts.
Ceramics, for bone grafting, 995
Cerclage wire
  defined, 958*b*
  in direct reduction, 989–990, 990*f*
  in intramedullary fixation, 1013
    application of, 1014, 1015*f*
      key concepts for, 1014*b*
    indications and biomechanical principles of, 1013–1014, 1013*f*
    postoperative care for, 1015
    proper placement of, 1014*f*
  for mandibular symphyseal fractures, 1045, 1046*f*
Cerebellar ataxia, 1331–1332, 1332*b*
Cerebellar herniation, Chiari-like malformation with, 1353–1354, 1354*f*
Cerebellar infarcts, 1448
Cerebellovestibular dysfunction, 1331–1332
Cerebellum, 1324*f*
Cerebral hemisphere, right, 1324*f*
Cerebral infarcts, 1448
Cerebral meningioma
  imaging of, 1359, 1359*f*
  prognosis for, 1361
Cerebral perfusion pressure, 1338
Cerebrospinal fluid (CSF) analysis, 1320–1322
  interpretation guidelines for, 1321, 1321*b*
  prior treatment and, 1321*b*
  via cisternal puncture, 1320–1321, 1320*f*
  via lumbar puncture, 1321–1322, 1321*f*
Cerebrovascular angiopathy, 1444
Cerenia (maropitant), for vomiting after removal of gastric foreign body, 419, 419*b*
Ceruminous gland adenocarcinoma, 325, 326*f*
Cervical disc disease, 1375–1381
  complications of, 1380
  diagnosis of, 1376–1378
    clinical presentation in, 1376
    history of, 1376
    imaging in, 1376–1377, 1377*f*–1378*f*
    laboratory findings in, 1377–1378
    physical examination findings in, 1376, 1377*f*
    signalment in, 1376
  differential diagnosis of, 1378
  general considerations and clinically relevant pathophysiology of, 1375, 1375*f*–1376*f*
  medical management of, 1378–1379
  prognosis for, 1381
  surgical treatment of, 1379, 1380*f*
Cervical mucocele, 358, 359*f*
Cervical myelopathy, Chiari-like malformation with, 1355
Cervical spinal nerves, surgical anatomy of, 1367
Cervical spine
  standard surgical approaches to, 1367–1373
  dorsal, 1370–1373
    advantages of, 1365–1366
    for cranial cervical laminectomy, 1372–1373, 1372*f*
    dissection on midline of superficial cervical musculature in, 1372–1373, 1372*f*
    for dorsal midcervical laminectomy, 1372–1373, 1373*f*
    elevation of muscle from spinous process and laminae in, 1372–1373, 1373*f*
    extent of defect in, 1373, 1374*f*
    positioning for, 1370–1372, 1371*f*
    separation of median raphe in, 1372–1373, 1372*f*
  indication for, 1367
  ventral, 1367–1370
    advantages of, 1365–1366
    exposure of longus colli musculature in, 1367–1370, 1369*f*
    exposure of vertebral bodies and intervertebral disk in, 1367–1370, 1369*f*
    extent of defect in, 1367–1370, 1370*f*
    incision for, 1367–1370, 1369*f*
    indication for, 1367
    midline separation of paired sternohyoideus muscle in, 1367–1370, 1369*f*
    positioning for, 1367, 1368*f*
    ventral slot procedure for, 1367–1370, 1370*f*
  surgical anatomy of, 1366–1367, 1367*f*–1368*f*
Cervical spine surgery, 1365–1403
  anesthetic considerations for, 1366
  antibiotics for, 1366
  for cervical disc disease, 1375–1381
Cervical spine surgery *(Continued)*
  for cervical spondylomyelopathy (Wobbler syndrome), 1381–1389
  complications of, 1375
  for craniocervical junction anomalies, 1389–1394
  definitions for, 1365
  general considerations for, 1365–1366
  healing of, 1373–1374
  postoperative care and assessment in, 1374–1375
  preoperative management of, 1366
  special age considerations for, 1375
  for spinal arachnoid diverticulum, 1394–1396
  for spinal neoplasia, 1396–1399
  for spinal trauma, 1399–1403
  standard surgical approaches to, 1367–1373
  dorsal
    advantages of, 1365–1366, 1370–1373
    for cranial cervical laminectomy, 1372–1373, 1372*f*
    dissection on midline of superficial cervical musculature in, 1372–1373, 1372*f*
    for dorsal midcervical laminectomy, 1372–1373, 1373*f*
    elevation of muscle from spinous process and laminae in, 1372–1373, 1373*f*
    extent of defect in, 1373, 1374*f*
    positioning for, 1370–1372, 1371*f*
    separation of median raphe in, 1372–1373, 1372*f*
  indication for, 1367
  ventral, 1367–1370
    advantages of, 1365–1366
    exposure of longus colli musculature in, 1367–1370, 1369*f*
    exposure of vertebral bodies and intervertebral disk in, 1367–1370, 1369*f*
    incision for, 1367–1370, 1369*f*
    indication for, 1367
    midline separation of paired sternohyoideus muscle in, 1367–1370, 1369*f*
    positioning for, 1367, 1368*f*
    ventral slot procedure for, 1367–1370, 1370*f*
  surgical anatomy for, 1366–1367, 1367*f*–1368*f*
  suture materials and special instruments for, 1374
Cervical spondylomyelopathy, 1381–1389
  classification of, 1381*t*
  complications of, 1388
  definitions for, 1381
  diagnosis of, 1382–1384, 1382*f*–1383*f*
  differential diagnosis of, 1384
  general considerations and clinically relevant pathophysiology of, 1381–1382
  medical management of, 1384
  prognosis for, 1388–1389

Cervical spondylomyelopathy *(Continued)*
surgical treatment of, 1384
dorsal procedures (laminectomy ± stabilization) for, 1386, 1389*f*
suture materials and special instruments for, 1386
ventral procedures (distraction-stabilization) for, 1384–1385, 1384*f*
cancellous screws in, 1385, 1385*f*
decompression of spinal cord in, 1386*b*, 1388*f*
full cortical allograft and polyvinylidene spinal plate in, 1385, 1387*f*
intramedullary pins in, 1385, 1386*f*
Steinmann pins and polymethylmethacrylate in, 1385, 1386*f*
undercutting of ventral slot in, 1384–1385, 1385*f*
Cervix, 725–726
Cesarean section, 735–738
anesthesia for, 724, 725*t*–726*t*
complications of, 745, 745*b*
drugs that initiate uterine contraction in, 738, 738*b*
en bloc resection in, 738
indications for, 735–736
neonatal care after, 738, 739*f*
with ovariohysterectomy, 736–737
without ovariohysterectomy, 737–738, 737*f*–738*f*, 738*b*
Cheiloplasty, 251, 252*f*, 331
after partial mandibulectomy, 336–337, 337*f*
antidrool, 251, 253*f*
Chemical autoregulation, 1338
Chemical fat saturation (FAT SAT) sequences, 169
Chemical indicators, for sterilization, 10, 10*f*–11*f*
Chemical injuries, 241–242, 241*f*
treatment of, 241–242
Chemical sterilization, 5–7
cold, 10
ethylene oxide for, 5–7
advantages and disadvantages of, 5, 6*t*
effectiveness of, 5–7
environmental and safety hazards with, 5–7
equipment for, 5, 9*f*
failure of, 5–7
strips and bag indicators for, 11*f*
Chemodectomas
diagnosis of, 823–824, 824*f*
pathophysiology of, 823
pericardiectomy of, 820
prognosis for, 823
surgical treatment of, 824–825
Chemosis, definition for, 284
Chemotactic factors, in wound healing, 180
Cherry eye, 284–286
complications of, 286
definition for, 281, 284
diagnosis of, 285
clinical presentation in, 285
laboratory findings in, 285
physical examination findings in, 285
Cherry eye *(Continued)*
differential diagnosis of, 285
general considerations and clinically relevant pathophysiology of, 284–285
medical management of, 285
postoperative care and assessment for, 286
prognosis for, 286
surgical techniques for, 285–286, 286*b*, 286*f*
surgical treatment for, 285
anesthesia for, 285
positioning for, 285
preoperative management, 285
surgical anatomy for, 285
suture materials and special instruments for, 286
CHG (chlorhexidine gluconate)
for sterile skin preparation, 38, 38*t*
for surgical scrub, 46*t*
Chiari-like malformation (CLM), 1353–1358, 1448–1449
definition for, 1353, 1354*f*
diagnosis of, 1354–1355, 1355*f*
differential diagnosis of, 1356
general considerations and clinically relevant pathophysiology of, 1353–1354, 1354*f*
medical management of, 1356
prognosis of, 1358
surgical treatment of, 1356
anesthesia for, 1356
positioning for, 1356
postoperative care and assessment for, 1358
preoperative management of, 1356
surgical anatomy for, 1356
surgical technique for, 1356–1357, 1357*f*
suture materials and special instruments for, 1357
Chisels, 54–55, 56*f*
Chitosan (HemoCon), for wound healing, 188
Chitosan dressings (Hemcon Patch), 197*t*–198*t*, 200
Chlorambucil (Leukeran), for feline chronic progressive polyarthritis, 1154*b*
Chloramphenicol (Chloromycetin), 81, 81*t*
for *Actinomyces* infection, 950*b*
hepatic dysfunction and, 572*b*
for rickettsial/ anaplasmal polyarthritis and bacterial L-forms, 1148*b*, 1149
ChloraPrep, for sterile skin preparation, 38–39, 39*b*, 39*f*
Chlorhexidine acetate-impregnated dressings, 200
Chlorhexidine diacetate, as wound cleanser, 188
Chlorhexidine gluconate (CHG)
for sterile skin preparation, 38, 38*t*
for surgical scrub, 46*t*
Chlorine compounds, as disinfectant, 5*t*
Chlormadinone acetate, for benign prostatic enlargement, 764*t*
Chloromycetin. *see* Chloramphenicol.
Choana, endoscopy of, 876, 876*f*
Choanal examination, endoscopy for, 159*b*
Cholangiocellular carcinomas, 566
Cholangiocellular neoplasms, 566
Cholangiohepatitis, 571
Cholangitis, 571
Cholecystectomy, 571, 574, 574*b*, 575*f*
for cholelithiasis, 580
laparoscopic, 574, 575*f*
Cholecystitis, 584–585
definition for, 584
diagnosis of, 584
differential diagnosis of, 584
general considerations and relevant pathophysiology of, 584
medical management of, 584
necrotizing, 571, 582
surgical treatment of, 584–585
Cholecystoduodenostomy, 571, 574–575, 577*f*
Cholecystoenterostomy, 571, 574–575, 577*f*
for cholelithiasis, 580
Cholecystojejunostomy, 571, 574–575, 577*f*
Cholecystotomy, 571, 573, 574*f*
laparoscopic-assisted, 574
Choledochoduodenostomy, 571, 574–575, 577*f*
Choledocholithiasis, 571
Choledocholiths, 578
Choledochotomy, 571, 574, 576*f*
for cholelithiasis, 580
Cholelithiasis, 571, 578–580
definitions for, 578
diagnosis of, 578–579, 578*b*, 579*f*
differential diagnosis of, 579
general considerations and clinically relevant pathophysiology of, 578
medical management of, 579
prognosis of, 580
surgical treatment of, 579
Choleliths, 578
general considerations and clinically relevant pathophysiology of, 578
Cholesteatomas, aural, 316
Chondrocyte, 1141
Chondroid degeneration, 1375, 1375*f*
Chondrosarcoma, 1300*t*
of lumbosacral region, 1436*f*
of thoracic wall, 912
Chondrosternal depression. *see* Pectus excavatum.
Chonechondrosternon. *see* Pectus excavatum.
CHPG. *see* Chronic hypertrophic pyloric gastropathy.
Chromic surgical gut sutures, 63*t*
Chronic antral mucosal hypertrophy, 425, 425*f*
Chronic degenerative disc disease, 1381*t*
Chronic hypertrophic gastritis. *see* Chronic antral mucosal hypertrophy.
Chronic hypertrophic pyloric gastropathy (CHPG), 425
Chronic intestinal disease, clinical signs of, 433, 434*t*
Chronic kidney disease (CKD)
anesthetic considerations with, 650–653, 652*t*–653*t*
defined, 650

Chronic kidney disease (CKD) *(Continued)*
preoperative management of, 650
staging system for, 650, 651*b*
Chronic renal failure (CRF), 650
Chronic valvular heart disease (CVHD), 798
Chronulac. *see* Lactulose.
Chyle, defined, 941
Chylothorax, 941–947
abnormalities associated with, 941*b*
clinical presentation of, 941
definitions for, 941
diagnosis of, 941–942
diagnostic imaging of, 942, 942*b*, 942*f*
differential diagnosis of, 942–943
general considerations and clinically relevant pathophysiology of, 941, 941*f*
history of, 941, 941*b*
laboratory findings in, 942
medical management of, 943–944, 943*b*
surgical treatment of, 944, 944*b*
active pleuroperitoneal or pleurovenous shunting for, 946–947, 946*b*, 946*f*
anesthesia for, 944
complications with, 947, 947*f*
mesenteric lymphangiography for, 945, 945*b*
positioning for, 944
postoperative care and assessment after, 947
preoperative management of, 944
prognosis of, 947
surgical anatomy for, 944
surgical techniques for, 945–947
suture materials and special instruments for, 947
thoracic duct ligation for, 945–946
Chylous effusions, 942, 942*b*, 942*t*
CicaCare (silicone gel sheets), 197*t*–198*t*
Cilia, 268
Ciliary ganglion, 1326*f*
Cine-MRI, 170
Ciprofloxacin, 82
Circle rebreathing system, 137, 137*f*
Circular external fixators, 1003–1008
application of, 1004–1007, 1005*b*–1006*b*
for angular limb deformity correction, 1006–1007, 1007*f*
for arthrodesis, 1005
for bone lengthening, 1005–1006, 1006*b*
for bone transport, 1006, 1006*f*
for fracture treatment, 1004–1005, 1004*f*
equipment and supplies for, 1003–1004, 1003*f*
for frame construction, 1004
rings as, 1003
wire fixation bolts as, 1003–1004
wire tensioner as, 1004, 1004*f*
wires as, 1003
wrenches as, 1004
hybrid, 1008
application of, 1008, 1009*f*
equipment and supplies for, 1008
Circular external fixators *(Continued)*
indications and biomechanical principles of, 1008
postoperative care for, 1008
indications and biomechanical principles of, 1003
postoperative care for, 1007–1008
for tibial diaphyseal fractures, 1124
Circular skin defects, 214–215, 214*f*
Circulatory shock, gastric ulceration and erosion due to, 428
Circumanal tumors, 489
Circumcostal gastropexy, 407–408, 408*b*, 409*f*–410*f*
Circumduction, definition for, 957
Circumferential tears, 1243–1244
Circumflex branch, 800–801, 800*f*
Cisapride (Propulsid), to improve urination, 701*t*
Cisatracurium
for cesarean section, 725*t*–726*t*
for fracture repair, 977*t*–978*t*
for liver surgery, 541*t*–542*t*
Cisternal puncture, cerebrospinal fluid analysis via, 1320–1321, 1320*f*
CJAs. *see* Craniocervical junction anomalies.
CKD (chronic kidney disease)
anesthetic considerations with, 650–651, 652*t*–653*t*
defined, 650
preoperative management of, 650
staging system for, 650, 651*b*
Claforan (cefotaxime), 80*t*
Clamps, 54–55, 55*f*
Clamshell forceps, 162, 162*f*
Clarithromycin, 81–82
Clavamox. *see* Amoxicillin plus clavulanate.
Claw surgery, 255–265
biopsy as, 255–257, 256*f*
deep digital flexor tenectomy as, 260, 261*f*
dewclaw removal as, 260–262
in adults, 260–262, 261*f*
breeds recommended for, 260, 260*b*
in puppies, 260, 261*f*
onychectomy (declawing) as, 257–260
alternatives to, 257
anesthetic considerations for, 257, 258*t*
defined, 257
dissection, 257*f*, 258–259
distal phalangeal anatomy for, 257*f*
nail clipper, 257*f*, 259
nerve blocks for, 257–258, 259*f*
postoperative care and complications of, 259–260, 260*f*
proper and improper lines of transection in, 257*f*
Clean areas, 21
Clean technique, 1
Clean wounds, 84, 85*t*
infection rate for, 84
prophylactic antibiotics for, 86
Clean-contaminated wounds, 84, 85*t*
prophylactic antibiotics for, 86–87
Cleaning
defined, 4
of instruments, 56–58, 56*b*
of surgical area
daily routines for, 23–25
of anesthesia and patient preparation room, 24–25, 24*b*
of operating room, 23–24, 24*b*
of recovery room, 25
of scrub sinks, 24, 24*b*
in room "turnover", 22–23
weekly and monthly cleaning routines for, 25
Cleansing scrub, preoperative
general, 37
sterile, 38–39, 38*b*
alcohol-based solutions as, 38–39, 38*t*, 39*b*
characteristics of ideal, 38, 38*b*
chlorhexidine as, 38, 38*t*
povidone-iodine as, 38, 38*t*, 39*f*
prevention of pooling of alcohol with, 39*b*
properties of, 38, 38*t*
Clear floor area, in operating room, 21
Cleft(s)
lateral, 342
primary, 342
closure of, 345, 347*f*
secondary, 342
Cleft lip, 342
Cleft palate, 342–346
complications of, 345
definition for, 342
diagnosis of, 342–343
clinical presentation in, 342
imaging in, 343
laboratory findings in, 343
physical examination findings in, 342, 343*b*
differential diagnosis of, 343
general considerations and clinically relevant pathophysiology of, 342, 342*f*
medical management of, 343
positioning for, 344
postoperative care and assessment after, 345
prognosis for, 346
surgical techniques for, 344–345
closure of hard palate defects, 344–345, 344*f*–346*f*, 345*b*
closure of primary clefts, 345, 347*f*
closure of soft palate defects, 345
reconstruction of soft palate hypoplasia, 345
surgical treatment of, 343–344
anesthesia for, 343
preoperative management of, 343
surgical anatomy for, 343–344
traumatic. *see* Oronasal fistula(e), acquired.
Clindamycin (Antirobe, Cleocin), 81*t*, 82
for *Actinomyces* infection, 950*b*
after foreign body removal, 166
for cauda equina surgery, 1428
for hepatic abscess, 565*b*
for peritonitis, 531, 531*b*

Clindamycin (Antirobe, Cleocin) *(Continued)*
for reproductive disorders, 726*b*
for septic arthritis, 1140*t*
for tracheal collapse, 871*b*
Clipping, preoperative, 36–37
Clitoral fossa, 725–726
Clitoris, 725–726
CLM. *see* Chiari-like malformation.
Clonus, 1334
Clopidogrel
for disseminated intravascular coagulation, 594, 594*b*
for pulmonary thromboembolism, 888*b*
Cloprostenol (Estrumate)
for pregnancy prevention or termination, 729*b*
for pyometra, 757*b*
Clorox Clean-Up, as disinfectant, 20*t*
Closed active drains, 191, 191*f*
Closed cardiac procedures, 788
Closed gloving, 47, 47*f*
Closed needle point, 64, 65*f*
Closed reduction, 989
defined, 958*b*, 989
indications for, 989*b*
Closed suction drains, 191–192, 191*f*
Closed wound bandages, 202
Closed-suction drainage, for peritonitis, 534–535, 535*f*
Closing wedge osteotomy, 1034–1035, 1034*f*
Clostridium spp., pyothorax due to, 948*t*
Clotrimazole, for nasal aspergillosis, 881–882, 882*f*
Clove hitch, for ovariohysterectomy, 728–729, 729*f*
CMAP (compound muscle action potential), 1318
CO_2. *see* Carbon dioxide.
Coagulation, in wound healing, 179–180
Coagulopathies, in hepatic disease, 540
Coaptation, definition for, 976
Coccygeal epidurals, 155
Cognitive dysfunction syndrome (CDS), 1444–1447
definitions for, 1444
diagnosis of, 1445, 1445*f*–1446*f*
differential diagnosis of, 1445
general considerations and clinically relevant pathophysiology of, 1444–1445
medical management of, 1445–1447
physical examination findings in, 1445
prognosis for, 1447
surgical treatment of, 1447
Coin retrieval forceps, 161, 162*f*
Colace (dioctyl sodium sulfosuccinate or docusate sodium), after prostatic or perineal surgery, 744*b*
Cold chemical sterilization, 10
Cold compression system, 110–111, 111*f*
Cold sterilization, 59
Cole tubes, 135
Colectomy, 466
subtotal, 470*b*, 470*f*, 474
for megacolon, 481, 481*b*
Colic artery, right, 468
Colitis, 477–479
colonic biopsy for, 479
complications of, 479
definition for, 477
diagnosis of, 478
clinical presentation in, 478
imaging in, 478
laboratory findings in, 478
physical examination findings in, 478
differential diagnosis of, 478
general considerations and clinically relevant pathophysiology of, 477–478
lymphocytic-plasmacytic, 477
medical management of, 478, 478*b*
postoperative care and assessment after, 479
prognosis for, 479
surgical technique for, 479
surgical treatment of, 478–479
anesthesia for, 478
positioning for, 479
preoperative management of, 478
surgical anatomy for, 479
suture materials and special instruments for, 479
Collagen, 1141
for bone grafting, 994
in wound healing, 180
Collagen dressings (Helix3 CM), 197*t*–198*t*, 200
Collagen injection, endoscopic, for urinary incontinence, 715, 715*f*
CollaRx (antibiotic-impregnated collagen sponges), 200
Collasate (hydrolyzed bovine collagen), 188
Collateral ligament(s)
palpation of, 962–963, 964*f*
surgical anatomy of, 1251, 1252*f*
Collateral ligament injury, 1250–1252
carpal subluxation from, 1206–1208
definitions for, 1206
diagnosis of, 1206–1207
clinical presentation in, 1206
imaging for, 1207, 1207*f*
laboratory findings in, 1207
physical examination for, 1206
differential diagnosis of, 1207
general considerations and clinically relevant pathophysiology of, 1206
medical management for, 1207
prognosis for, 1208
surgical treatment for, 1207, 1208*f*
definition for, 1250–1252
diagnosis of, 1250–1251
clinical presentation in, 1250
imaging in, 1251, 1251*f*
laboratory findings in, 1251
physical examination in, 1250, 1250*f*, 1251*b*
differential diagnosis of, 1251
general considerations and clinically relevant pathophysiology of, 1250
medical management for, 1251
prognosis for, 1252
surgical treatment for, 1251, 1251*b*
anesthesia for, 1251
Collateral ligament injury *(Continued)*
for lateral collateral ligament injury, 1252
for medial collateral ligament injury, 1251–1252, 1253*f*
positioning for, 1251
postoperative care after, 1252
preoperative management of, 1251
surgical anatomy for, 1251, 1252*f*
suture materials and special instruments for, 1252
Collimators, 170
Colloid solutions, 32–33, 33*b*
albumin in, 33
consequences of hypoalbuminemia and, 33*b*
human serum, 32*t*, 33
dextran 70 in, 33
hetastarch in, 33
indications for, 32*t*
for peritonitis, 532–533
Colon. *see also* Large intestine.
ascending, 468, 468*b*
descending, 468, 468*b*
transverse, 468, 468*b*
Colonic bacteria, 473, 473*b*
Colonic biopsy, for colitis, 479
Colonic urinary diversion, 695–696, 697*f*
Colonoileoscopy, 159*b*, 434–435
Colonoscopy
defined, 158
equipment for, 162, 162*f*
indications for, 160
of intestinal intussusception, 460
of intestinal neoplasia, 476
Colopexy, 466, 469–470, 469*f*
Colorado Acute Pain Scale, 144, 146*f*–147*f*
Colorectal neoplasia, 475–477
complications of, 477
definitions for, 475
diagnosis of, 475–476
clinical presentation in, 475
imaging in, 476
laboratory findings in, 476
physical examination findings in, 475–476
differential diagnosis of, 476
endoscopic biopsy of, 476
general considerations and clinically relevant pathophysiology of, 475
medical management of, 476
postoperative care and assessment after, 477
prognosis for, 477
surgical technique for, 476–477
surgical treatment of, 476
anesthesia for, 476
positioning for, 476
preoperative management of, 476
surgical anatomy for, 476
suture materials and special instruments for, 477
Colostomy, 466, 471–473
diverting loop, 473
end-on, 473
Colposuspension, for urinary incontinence, 714

Colyte (polyethylene glycol electrolyte solution), for large intestinal and rectal surgery, 467, 467*b*
Coma, 1323, 1324*t*
Combine roll, for intermediate layer of bandage, 200–201
Combined V technique, for circular skin defects, 214, 214*f*
Comminuted fractures, 983–984, 984*f*
  bone healing in, 1030
  distal femoral, 1113
  femoral diaphyseal
    with multiple fragments, 1107–1108, 1109*f*
    with one or two large butterfly fragments, 1107, 1108*f*
  humeral diaphyseal, 1055*f*
    with large butterfly fragment (reducible), 1058, 1059*f*
    with multiple fragments, 1058–1059, 1060*f*
  intramembranous bone healing of, 1027, 1028*f*
  mandibular, 1045–1047, 1046*f*
  metacarpal and metatarsal, 1088*f*–1089*f*, 1090, 1090*b*
  plate-rod combination for, 1022*f*
  of scapular body, 1051*f*
  tibial diaphyseal
    with large butterfly fragment, 1126, 1127*f*
    with multiple fragments, 1126, 1127*f*
Comminution, definition for, 976
Common bile duct, 543*f*
  identification of, 574
  injuries of, repair of, 576, 578*f*
  stenting of, 573
  surgical anatomy of, 543*f*, 572*f*, 573
Common carotid arteries, 794–795
Common carotid artery, 616*f*
Common digital extensor muscle, 1078*f*
Common hepatic artery, 543, 543*f*
Common pool theory, 143–144
Communication, with client, 27
Comorbidities, definition for, 976
Compartment syndrome, 1280
Complementary therapies, for cognitive dysfunction syndrome, 1445–1447
Complete fractures, 983–984
Complex mucoceles, 358
Complex repetitive discharges, in electromyography, 1317–1318, 1317*t*
Compliance, 1338
Composite flaps
  defined, 217
  muscle, 228–231
    caudal sartorius, 230, 230*f*
    cranial sartorius, 229–230, 230*f*
    external abdominal oblique, 229, 229*f*
    flexor carpi ulnaris, 230–231, 231*f*
    temporalis, 231, 232*f*
  myocutaneous, 226–228, 226*b*
    cutaneous trunci, 227, 227*f*
    latissimus dorsi, 227, 227*f*
    platysma, 226
    trapezius osteo-, 228, 228*f*
Compound action potentials, 1319
Compound flaps. *see* Composite flaps.
Compound muscle action potential (CMAP), 1318
Compression plates, 958*b*
  application of, 1021–1022, 1021*f*
  dynamic, 1018*f*
    application of, 1021*f*
    limited-contact, 1018, 1018*f*
  locking, 1017–1018, 1017*f*
Compression screws, 1017
  application of, 1019–1020, 1020*b*, 1020*f*
Computed tomography (CT)
  of cervical disc disease, 1376–1377, 1377*f*
  clinical applications of
    for biopsy procedures, 175, 177*f*
    for cardiac studies, 175
    for musculoskeletal system, 171, 172*f*–173*f*
    for portosystemic shunts, 174–175, 174*f*
    for pulmonary neoplasia, 175, 176*f*
    for pulmonary thromboembolism, 175
    for tympanic bullae, 172–174, 173*f*–174*f*
  of fragmented coronoid process, 1175–1176, 1176*f*
  of lung lobe torsion, 906, 906*f*
  physics of, 170
Computed tomography angiography, of portosystemic shunt, 552
Computed tomography (CT)-based excretory urography, 174–175
Concentric contraction, 106
Conchal cartilage graft repair, for acquired oronasal fistula, 350, 353*f*
Conditioned media, 972–973
  defined, 968–970
Confluens sinus, 1343*f*
Congenital cricopharyngeal achalasia. *see* Cricopharyngeal achalasia.
Congenital diaphragmatic hernia. *see* Peritoneopericardial diaphragmatic hernia.
Congenital elbow luxation, 1200–1202
  definition for, 1200
  diagnosis of, 1200–1201
  differential diagnosis of, 1201
  general considerations and clinically relevant pathophysiology of, 1200, 1200*f*–1201*f*
  medical management for, 1201, 1201*f*
  prognosis for, 1202
  surgical treatment for, 1201–1202, 1201*b*
Congenital elbow malformation. *see* Congenital elbow luxation.
Congenital extrahepatic portosystemic shunts (CEPSSs), 550
  history of, 552, 552*b*
  physical examination findings in, 552
  prognosis for, 563
  signalment for, 551
  ultrasound for, 552–553
Congenital hydrocephalus, 1347–1350
  clinical presentation of, 1348
  definition for, 1347
  diagnosis of, 1348
  diagnostic imaging of, 1348, 1348*f*
  differential diagnosis of, 1349
Congenital hydrocephalus *(Continued)*
  general considerations and clinically relevant pathophysiology, 1347–1348
  laboratory findings in, 1348
  medical management of, 1349, 1349*t*
  physical examination findings in, 1348, 1348*f*–1349*f*
  prognosis of, 1350
  surgical treatment of, 1349–1350, 1350*f*
    anesthesia for, 1349
    positioning for, 1349–1350
    postoperative care and assessment after, 1350, 1351*f*–1352*f*
    preoperative management of, 1349
    prognosis of, 1350
    surgical anatomy for, 1349
    surgical technique for, 1350, 1351*f*
    suture materials and special instruments for, 1350
Congenital hypertrophic stenosis. *see* Pyloric stenosis.
Congenital osseous malformation, 1381*t*
Congenital pyloric muscle hypertrophy. *see* Pyloric stenosis.
Congenital tracheal stenosis, 868
Congestive heart failure, medical management of, 809, 809*b*
Conjunctiva, 289
  healing of, 283
  surgical anatomy of, 282, 282*f*–283*f*
Conjunctiva surgery, 281–291
  anesthetic considerations for, 281–282
  antibiotics for, 282, 282*b*
  complications of, 284
  postoperative care and assessment after, 284
  preoperative concerns with, 281, 281*b*
  special age considerations for, 284
  surgical site preparation for, 281, 281*b*
  third eyelid flap for, 283, 284*f*
Conjunctival flap, 289–290, 290*b*
  360-degree, 290, 291*f*
  hood, 290, 290*f*
Connell suture pattern, 70–71, 70*f*
Conscious proprioception, 1332–1333
Constipation
  definition for, 479
  medical management of, 480–481, 481*b*
Constrictive pericarditis. *see* Pericardial constriction.
Constrictor vestibule muscles, 725–726
Contact healing, 1026, 1027*f*
Contact layer, of wound dressing
  factors in selection of, 195, 195*b*
  hydrophilic, 195–196, 195*b*
  selection of
    based on purpose, 195, 196*t*
    based on wound characteristics, 195, 197*t*
  types of, 195, 197*t*–198*t*
  wound contraction and, 195, 195*b*
Contaminated wounds, 84, 85*t*
  infection rate for, 84
  prophylactic antibiotics for, 86–87
  sutures for, 66
Contamination, 2*b*
  sources of, 1

Continuous correction, 1079
Continuous distraction, 1079
Continuous passive motion, for cartilage defects, 1143
Continuous suture patterns, 69–71
  Connell, 70–71, 70*f*
  Cushing, 70–71, 70*f*
  Ford interlocking, 70, 70*f*
  Lembert, 70, 70*f*
  running, 69–70, 70*f*
  simple, 69–70, 70*f*
Continuous thoracic suction, 924, 925*f*–926*f*
Continuous-rate infusion (CRI), for analgesics and anesthetics, 144*b*
Contracture
  defined, 1288–1289, 1291
  hamstring, 1292
  infraspinatus fibrotic, 1288–1289
    definitions for, 1288
    diagnosis of, 1288, 1289*f*
    differential diagnosis of, 1288–1289
    general considerations and clinically relevant pathophysiology, 1288
    medical management of, 1289
    postoperative care for, 1289
    prognosis of, 1289
    surgical treatment of, 1289
  quadriceps, 1289–1291
    definitions for, 1289
    diagnosis of, 1290, 1290*f*
    differential diagnosis of, 1290
    general considerations and clinically relevant pathophysiology, 1289–1290
    medical management of, 1290
    physical rehabilitation for, 1290
    postoperative care and assessment for, 1291
    prognosis of, 1291
    surgical treatment for, 1290–1291
  semitendinosus, 1292
Contrast agents, 170
Contrast-enhanced magnetic resonance angiography (CE-MRA), 174–175, 175*f*
Conus medullaris, 1428
Convenia (cefovecin), 80*t*
Coonhound paralysis, 1463
Copa (polyurethane foam dressings), 197*t*–198*t*, 199
Copperhead, 244
Coral snake, 244
Core biopsy, of liver, 544, 544*f*
Core strengthening, as therapeutic exercise, 119
Corkscrew tails, 252, 254*f*
Cornea, 282
  surgical anatomy of, 289, 289*f*
Corneal reflex, 1325, 1327*f*
Corneal ulcers, 286–291
  complications of, 291
  conjunctival flap in, 289–290, 290*b*
    360-degree, 290, 291*f*
    hood, 290, 290*f*
  diagnosis of, 287
    clinical presentation in, 287
    laboratory findings in, 287
Corneal ulcers *(Continued)*
    physical examination findings in, 287, 287*b*
  differential diagnosis of, 287–288
  general considerations and clinically relevant pathophysiology, 286–287
  medical management for, 288
  postoperative care and assessment for, 290–291
  prognosis for, 291
  surgical treatment of, 288–289
    anesthesia for, 289
    positioning for, 289
    preoperative management of, 289, 289*b*
  suture materials and special instruments for, 290
Corniculate cartilage, 839*f*
Corniculate process, 839*f*
Coronary sinus, 794–795
Coronary vessels, 800–801
Coronoid process, fragmented, 1174–1180, 1174*t*
  definition for, 1174
  diagnosis of, 1175–1176
    clinical presentation in, 1175
    differential diagnosis of, 1176
    imaging in, 1175–1176, 1175*b*, 1175*f*–1176*f*
    laboratory findings in, 1176
    physical examination in, 1175
  general considerations and clinically relevant pathophysiology, 1174–1175, 1174*b*–1175*b*
  medical management of, 1176, 1177*b*
  prognosis of, 1180
  surgical treatment of, 1176–1179
    anesthesia for, 1177
    arthroscopic treatment of, 1177, 1178*f*–1179*f*
    complications of, 1180
    open, 1179–1180
    postoperative care and assessment after, 1180
    preoperative management of, 1177
    suture materials and special instruments for, 1180
Coronoidectomy, subtotal
  arthroscopic, 1178, 1179*f*
  for medial compartment disease, 1185
  open, 1180
Corpectomy, partial lateral, 1404
Corpus cavernosum penis, 727
Corpus spongiosum, 727
Correction
  acute, 1079
  continuous, 1079
Corrective osteotomies, 958*b*, 1033
  for deformities, 1034–1035, 1034*f*
  indications for, 1034*t*
  for joint incongruity, 1035, 1035*f*
Corrective osteotomy, 1079
Corrosion, of instruments, 55, 57*t*
Corrosives, chemical injuries due to, 241
Cortical bone allografts
  for bone grafting, 993
  with carpal arthrodesis, 1305, 1308*f*
Cortical bone allografts *(Continued)*
  for cervical spondylomyelopathy, 1385, 1387*f*
Cortical bone autografts, for bone grafting, 993
Cortical screws, 1017, 1017*f*
  for craniocervical junction anomalies, 1392, 1393*f*
Corticosteroid-responsive meningitis/arteritis, 1455
Corticotomy, for bone lengthening, 1005
Cotton muslin, for surgical pack wrapping, 12*t*
Cottonmouth water moccasin, 244
Coughing, in pleural effusion, 941, 941*b*
Coumarin, for lymphedema, 636
Coxa valga, 1261
Coxofemoral disarticulation, for bone neoplasia, 1303–1304, 1306*f*
Coxofemoral joint
  luxation of, 1209
  synovial fluid collection from, 1136*f*
Coxofemoral joint capsule, reconstruction of, 1223, 1223*b*, 1224*f*
Coxofemoral joint diseases, 1209–1227
  coxofemoral luxation as, 1220–1225
  hip dysplasia as, 1209–1220
  Legg-Perthes disease, 1225–1227, 1226*f*
Coxofemoral joint reconstruction, 1224, 1224*f*
Coxofemoral luxation, 1220–1225
  closed reduction of
    caudoventral luxation, 1222, 1222*f*
    craniodorsal luxation, 1221, 1222*f*
  definition for, 1209, 1220
  diagnosis of, 1220
    clinical presentation in, 1220
    differential diagnosis of, 1221
    imaging in, 1220, 1221*f*
    laboratory findings in, 1220
    physical examination in, 1220, 1220*f*–1221*f*
  general considerations and clinically relevant pathophysiology, 1220, 1220*b*
  medical management for, 1221–1222
    closed reduction of a caudoventral luxation in, 1222, 1222*f*
    closed reduction of a craniodorsal luxation in, 1221, 1222*f*
    Ehmer slings in, 1221–1222, 1222*f*
    hind limb hobbles in, 1222, 1223*f*
  prognosis for, 1225
  surgical treatment for, 1223
    anesthesia for, 1223
    capsule reconstruction in, 1223, 1223*b*, 1224*f*
    exploration of the hip joint in, 1223, 1223*b*
    joint reconstruction in, 1224, 1224*f*
    positioning for, 1223
    postoperative care after, 1225
    preoperative management of, 1223
    surgical anatomy for, 1223
    translocation of the greater trochanter in, 1225, 1225*f*
Coxofemoral subluxation, 1209
Cranial abdominal vessels, 587

Cranial caudal angulation, 1081
Cranial cervical laminectomy
  for cranial cervical laminectomy, 1372–1373, 1372*f*
  dissection on midline of superficial cervical musculature in, 1372–1373, 1372*f*
  for dorsal midcervical laminectomy, 1372–1373, 1373*f*
  elevation of muscle from spinous process and laminae in, 1372–1373, 1373*f*
  extent of defect in, 1373, 1374*f*
  positioning for, 1370–1372, 1371*f*
  separation of median raphe in, 1372–1373, 1372*f*
Cranial cruciate ligament (CCL), 1227, 1227*f*
Cranial cruciate ligament rupture, 1227–1243
  definitions for, 1227
  diagnosis of, 1228–1231
    arthroscopy in, 1230–1231, 1231*f*
    clinical presentation of, 1228
    diagnostic imaging in, 1229–1231, 1230*f*
    laboratory findings in, 1231
    physical examination in, 1228–1229, 1229*b*, 1229*f*
      cranial drawer test in, 1229
      tibial compression test in, 1229, 1229*f*
  differential diagnosis in, 1231
  general considerations and clinically relevant pathophysiology, 1227–1228, 1227*b*, 1227*f*–1228*f*
    craniomedial band in, 1227
  medical management for, 1231–1232, 1232*b*
  in multiple ligament injury, 1254*f*
  prognosis for, 1243
  surgical treatment for, 1232–1234, 1232*t*
    anesthesia for, 1233
    complications of, 1243
    extracapsular reconstruction for, 1232
    intracapsular reconstruction for, 1232
    lateral approach to, 1234, 1235*f*
    lateral extracapsular stabilization for, 1235–1237, 1236*f*
    medial approach to, 1235, 1236*f*
    positioning for, 1234
    postoperative care after, 1243
    preoperative management of, 1233
    surgical anatomy for, 1233–1234, 1234*f*
    suture materials and special instruments for, 1243
    tibial plateau leveling osteotomy for, 1232, 1233*f*, 1238–1240
      radiographic assessment for, 1238–1239, 1238*f*–1239*f*, 1239*t*
      surgical technique for, 1239–1240, 1240*f*–1242*f*
    tibial tuberosity advancement for, 1241–1243
      radiographic assessment for, 1241
      surgical technique for, 1241–1243, 1242*b*, 1244*f*
    tibial wedge osteotomy for, 1232–1233, 1233*f*, 1240–1241
Cranial cruciate ligament rupture *(Continued)*
    radiographic assessment for, 1240, 1242*f*
    surgical technique for, 1240–1241, 1243*f*
  tightrope stabilization for, 1237–1238, 1237*f*
Cranial cruciate surgery local blocks, 153
Cranial drawer, 958*b*, 1227
Cranial drawer test, 1229
Cranial laryngeal artery, 839
Cranial laryngeal nerve, 839
  thyroid branch of, 616*f*
Cranial laryngeal vein, 839
Cranial mediastinal masses, differential diagnosis for, 952–953, 952*b*
Cranial mesenteric artery, 604*f*
Cranial nerves, 1323–1328, 1325*t*, 1326*f*
  I (olfactory), 1324–1325, 1325*t*
  II (optic), 1324–1325, 1325*t*, 1326*f*
  III (oculomotor), 1324–1325, 1325*t*, 1326*f*
  IV (trochlear), 1324–1325, 1325*t*
  V (trigeminal), 1325, 1325*t*, 1327*f*
  VI (abducens), 1325, 1325*t*
  VII (facial), 1325, 1325*t*, 1327*f*
  VIII (vestibulocochlear), 1325, 1325*t*, 1327*f*
  IX (glossopharyngeal), 1325–1328, 1325*t*, 1328*f*–1329*f*
  X (vagus), 1325–1328, 1325*t*, 1328*f*–1329*f*
  XI (accessory), 1325–1328, 1325*t*, 1328*f*–1329*f*
  XII (hypoglossal), 1325–1328, 1325*t*, 1329*f*
Cranial pancreaticoduodenal artery, 603, 604*f*
Cranial pubic ligament, 520
Cranial pubic ligament hernia, 519, 519*f*
  surgical techniques for, 521, 521*f*–522*f*
Cranial rectal artery, 484
Cranial sartorius muscle flap, 229–230, 230*f*
Cranial superficial epigastric axial pattern flap, 225
Cranial thyroid artery, 616–617, 616*f*
Cranial thyroid vein, 616*f*
Cranial tibial thrust (CTT), 1227
Cranial vesical artery, 689*f*
Craniocervical junction anomalies (CJAs), 1389–1394
  complications of, 1394
  definitions for, 1389
  diagnosis of, 1390–1391, 1391*f*
  differential diagnosis of, 1391
  general considerations and clinically relevant pathophysiology of, 1389–1390, 1390*f*
  medical management of, 1391
  prognosis for, 1394
  surgical treatment of, 1391–1392
    dorsal fixation methods for, 1392, 1393*f*
    Kirschner wires and PMMA in, 1392, 1392*f*
    multiple pins and screws in, 1392, 1393*f*
Craniocervical junction anomalies (CJAs) *(Continued)*
    PMMA in, 1392, 1393*f*
    positioning for, 1392
    reduction of atlantoaxial subluxation in, 1392, 1392*f*
    suture materials and special instruments for, 1394
Craniomandibular osteopathy, 1298–1299, 1299*b*, 1299*f*
Craniomedial band, of cranial cruciate ligament, 1227
Craniomedial tibia, surgical approach to, 1132
Craniotomy
  defined, 1338
  rostrotentorial (lateral), 1338, 1343, 1345*f*
  suboccipital, 1338, 1344, 1347*f*
  transfrontal, 1338, 1344, 1346*f*
Crawling, as therapeutic exercise, 119
C-reactive protein (CRP), in peritonitis, 528–529
Creatinine, high, 28*t*
Cremaster muscle, 727
Crepitation, 958*b*
Crescentic skin defects, 217, 217*f*
CRF (chronic renal failure), 650
CRI (continuous rate infusion), for analgesics and anesthetics, 144*b*
Cribriform, 1343*f*
Cricoid cartilage, 838, 839*f*, 1369*f*
Cricopharyngeal achalasia, 391–394
  complications of, 394
  definition for, 391
  diagnosis of, 392
    clinical presentation in, 392
    imaging in, 392
    laboratory findings in, 392
    physical examination findings in, 392
  differential diagnosis of, 392
  general considerations and clinically relevant pathophysiology of, 391–392
  medical treatment of, 392
  postoperative care and assessment after, 394
  prognosis for, 394
  surgical technique for, 393–394, 394*f*
  surgical treatment of, 393
    anesthesia for, 393
    positioning for, 393
    preoperative management of, 393
    surgical anatomy for, 393, 393*f*
Cricopharyngeal asynchrony. *see* Cricopharyngeal achalasia.
Cricopharyngeal dysfunction. *see* Cricopharyngeal achalasia.
Cricopharyngeal dysphagia. *see* Cricopharyngeal achalasia.
Cricopharyngeal myectomy, 393, 394*f*
Cricopharyngeus muscle, 839*f*
Cricothyroid ligament, 838
Cricothyroideus muscle, 1369*f*
Crile hemostat forceps, 53–54, 53*f*
Crofab (antivenin), 245–246
Cross pins, partial carpal arthrodesis with, 1206
Cross-contamination, 2*b*

Crossed extensor reflex, 1336
Crossed intramedullary pins, for cervical spondylomyelopathy, 1385, 1386*f*
Crotalidae, 244
Crotalidae Polyvalent Immune Fab (antivenin), 245–246
CRP (c-reactive protein), in peritonitis, 528–529
Cruciate injury, palpation for, 964–965
Cruciate suture pattern, 69, 69*f*
Crush injuries, 183
  of paw, 263–265
Cryoprecipitate, 32*t*, 33
Cryotherapy, 110–111, 111*b*, 111*f*
Cryptogenic strokes, 1448
Cryptorchid castration, 734, 735*b*, 736*f*
Cryptorchidism, 734
Crystalloid solutions, 31–32, 32*t*
  choice of, 31
  examples of, 31, 32*t*
  indications for, 32*t*
  potassium supplementation with, 31, 32*t*
Crystalluria, 700
CSF analysis. *see* Cerebrospinal fluid (CSF) analysis.
CT. *see* Computed tomography.
Cubicin (daptomycin), 80–81
Cuneiform cartilage, 839*f*
Cuneiform processes, 838, 839*f*
Cuprimine (D-penicillamine), for urinary calculi, 705*b*
Curafil (hydrogel dressing), 197*t*–198*t*, 198–199
Curagel (hydrogel dressing), 197*t*–198*t*, 198–199
Curasalt (hypertonic saline) dressing, 196–198, 197*t*–198*t*
Curasorb (calcium alginate dressings), 197*t*–198*t*, 199
Curettes, 54–55
Curity (hypertonic saline) dressing, 196–198, 197*t*–198*t*
Curved needles, 64, 65*f*
Cushing disease, 586
Cushing suture pattern, 70–71, 70*f*
Cutaneous plexus, 179
Cutaneous trunci reflex, 1336, 1336*f*
Cutting needles, 64, 65*f*
CVHD (chronic valvular heart disease), 798
Cyanoacrylate tissue adhesives (Vetbond, LiquiVet, GLUture), 66–67
Cyclophosphamide (Cytoxan), for feline chronic progressive polyarthritis, 1154*b*
Cyclosporine (Atopica, Neoral)
  for immune-mediated polyarthritis, 1151–1152, 1151*b*
  for noninfectious inflammatory disease, 1455*b*
  for perianal fistula, 502–503, 503*b*
  for rheumatoid arthritis, 1153*b*
Cyproterone acetate, for benign prostatic enlargement, 764*t*
Cyst(s), 933
  dentigerous, 356
  hepatic. *see* Hepatic cysts.
  honey. *see* Salivary mucoceles.
Cyst(s) *(Continued)*
  interdigital, 250
    treatment of, 250
  intracranial arachnoid, 1350–1353
    definition for, 1350
    diagnosis of, 1351–1352, 1352*f*
    differential diagnosis of, 1352–1353
    general considerations and clinically relevant pathophysiology, 1350–1351
    medical management of, 1353
    postoperative care and assessment for, 1353, 1353*f*
    prognosis of, 1353
    surgical technique for, 1353
    surgical treatment of, 1353
    suture materials and special instruments for, 1353
  mediastinal, 951–954
  mucocele *vs.*, 358
  ovarian, 728*f*
  prostatic, 763*t*, 768–771
    definitions for, 768
    diagnosis of, 768–769, 768*f*, 769*b*
    differential diagnosis of, 769
    general considerations and clinically relevant pathophysiology, 768, 768*f*
    medical management of, 769
    paraprostatic (periprostatic), 768, 769*f*
    parenchymal, 768
    prognosis for, 771
    surgical treatment of, 769
      anesthesia for, 769
      positioning for, 769
      postoperative care and assessment of, 771
      preoperative management of, 769
      surgical technique for, 769–771, 769*f*–770*f*
  pseudo-, pancreatic, 606–609
    definitions for, 606–607
    diagnosis of, 607–608, 607*f*, 608*b*
    differential diagnosis of, 608
    general considerations and clinically relevant pathophysiology, 607, 607*b*, 607*f*
    medical management of, 608
    prognosis for, 609
    surgical treatment of, 608, 609*b*
  salivary. *see* Salivary mucoceles.
  spinal arachnoid. *see* Diverticulum, spinal arachnoid.
  thymic branchial, 951–954
Cystadenocarcinoma, ovarian, 728*f*
Cystectomy, 678
Cystic duct, 572, 572*f*
Cystic endometrial hyperplasia-pyometra complex. *see* Pyometra.
Cystic thyroid, preoperative management of, 616
Cystine uroliths, 701
  signalment of, 702–703
  treatment and prevention of, 702*t*
Cystography, double-contrast, of uroliths, 703, 703*b*
Cystolithectomy, 678, 700
Cystolithiasis, 678, 700
Cystometrograms, 722
Cystopexy, for urinary incontinence, 714–715, 715*f*
Cystoscopic retrieval, of bladder and urethral calculi, 704
Cystoscopically-guided laser ablation, for ectopic ureters, 667
Cystoscopy, 158, 159*b*, 163
  of ectopic ureters, 665–666, 666*f*, 712, 713*f*
  laparoscopically assisted, for bladder and urethral calculi, 704
Cystostomy
  defined, 678
  temporary, 678, 685–686, 687*f*
Cystotomy
  defined, 678, 700
  surgical technique for, 685–687, 685*b*, 687*f*
Cystourethrogram
  of bladder rupture, 699*f*
  of transitional cell carcinoma, 709, 709*f*
Cystourethropexy, for urinary incontinence, 714–715, 715*f*
Cytobin (L-triiodothyronine), for hypothyroidism, 615*b*
Cytologic preparations, with endoscopy, 165
Cytologic studies, endoscopy for
  cytologic preparations for, 165
  indication for, 160
  washes for, 160, 165
Cytomel (L-triiodothyronine), for hypothyroidism, 615*b*
Cytosine arabinoside, for noninfectious inflammatory disease, 1455*b*
Cytotec (misoprostol), for gastric ulceration and erosion, 429, 429*b*
Cytoxan (cyclophosphamide), for feline chronic progressive polyarthritis, 1154*b*

D

Dacron (polyester) sutures, 62, 63*t*
Dakin's solution, as wound cleansers, 189
Dalfopristin and quinupristin (Synercid), as drug of last resort, 82–83
Dalteparin (Fragmin), for pulmonary thromboembolism, 888*b*
Dalteparin (low-molecular-weight heparin)
  for disseminated intravascular coagulation, 638*b*
  for peritonitis, 531, 531*b*
Damage, of instruments, 55, 57*t*
Daptomycin (Cubicin), as drug of last resort, 82–83
Dark brown stain, on instruments, 58*t*
DeBakey forceps, 52–53, 796–797, 796*f*
Debarking, 845–846
  complications of, 845
  defined, 833
  with laryngotomy approach, 845–846, 847*f*
  with oral approach, 845, 846*f*
Debridement, 185–186
  autolytic, 182, 185
  bandage (mechanical), 185
  biosurgical, 186

Debridement *(Continued)*
enzymatic, 185–186
surgical, 185
for wounds, 238, 238*f*
Débridement phase, of wound healing, 180
Decerebellate rigidity, 1330–1331
Decerebrate rigidity, 1330–1331, 1331*f*
Declawing, 257–260
alternatives to, 257
anesthetic considerations for, 257, 258*t*
defined, 257
dissection, 257*f*, 258–259
distal phalangeal anatomy for, 257*f*
nail clipper, 257*f*, 259
nerve blocks for, 257–258, 259*f*
postoperative care and complications of, 259–260, 260*f*
proper and improper lines of transection in, 257*f*
Decontamination, 2*b*
Deep circumflex iliac artery, 223*f*
Deep circumflex iliac axial pattern flap, 225
Deep digital flexor tenectomy, 260, 261*f*
Deep femoral artery and vein, 527*f*
Deep gluteal muscle, 1112*f*
Deep pain perception (DPP), with thoracolumbar disc disease, 1414–1415
Deep partial-thickness burns, 237
Deep zone, of articular cartilage, 1141–1142, 1142*f*
Degenerative disc disease, chronic, 1381*t*
Degenerative joint disease (DJD), 1143–1146
asymptomatic, 1145*b*
definition for, 1143
diagnosis of, 1144
arthroscopy in, 1144, 1145*f*
clinical presentation in, 1144
imaging in, 1135*t*, 1144, 1144*f*
differential diagnosis of, 1145
general considerations and clinically relevant pathophysiology of, 1144
laboratory findings in, 1144
medical management of, 1145
antiinflammatory drugs as, 1140*t*
chondroprotective agents for, 1137
glucocorticoids for, 1145, 1145*b*
NSAIDs for, 1145, 1145*b*
principles of, 1137*b*
physical examination in, 1144
primary, 1144
prognosis for, 1146, 1146*b*
secondary, 1144
surgical treatment of, 1145–1146
Degenerative lumbosacral stenosis (DLSS), 1431–1434
complications of, 1433
definition for, 1431
diagnosis of, 1431–1433
clinical presentation in, 1431–1432
imaging in, 1432–1433, 1432*f*
laboratory findings in, 1433
physical examination findings in, 1432
differential diagnosis of, 1433
general considerations and clinically relevant pathophysiology, 1431, 1431*f*
medical management of, 1433
Degenerative lumbosacral stenosis (DLSS) *(Continued)*
prognosis for, 1433–1434
surgical technique for, 1433, 1435*f*
surgical treatment of, 1433, 1434*f*
anesthesia for, 1433
positioning for, 1433
preoperative management of, 1433
surgical anatomy for, 1433
suture materials and special instruments for, 1433
Degenerative mitral valve disease (DMVD), 798
Degenerative myelopathy (DM), 1447–1448, 1447*b*
Degloving injuries, 183, 1266
of paw, 263–265
Dehiscence, 194
incisional hernias, 518
Dehydrating chemical, injuries due to, 241
Dehydration, obesity and, 600*b*
Delay phenomenon, 217–218
Delayed primary wound closure, 193
Delayed union, 958*b*, 1031
Delaying flap transfer, 217–218
Delicate scissors, 50
Delmadinone acetate, for benign prostatic hyperplasia, 763–764
Deltoideus muscle, 1049*f*–1050*f*, 1063*f*
Dementia, in cognitive dysfunction syndrome, 1445
Demineralized bone matrix, for bone grafting, 994
Denaturizing agents, injuries due to, 241
Dens, apical ligament of, 1368*f*
Dental blocks, 151
Dentigerous cysts, 356
Depilatory creams, preoperative, 36–37
Depo-Provera (medroxyprogesterone acetate), for benign prostatic enlargement, 763–764, 764*t*
Depo-testosterone (Testosterone cypionate), for urinary incontinence, 713–714, 714*b*
L-Deprenyl (selegiline; Anipryl, Atapryl, Carbex, Eldepryl, Zelapar), for cognitive dysfunction syndrome, 1445–1447
Deracoxib (Deramaxx), 148*t*–149*t*, 150
Dermabond (2-octylcyanoacrylate), 67
Dermacea (rayon/polyethylene glycol dressing), 197*t*–198*t*
Dermalon (polyamide) sutures, 62, 63*t*
Dermatitis
acral lick, 248–249, 248*f*
treatment of, 249
intertriginous, due to redundant skin folds, 251
Dermatome, 140
Dermatoses, psychogenic, 248–249, 248*f*
treatment of, 249
Dermis, 179
Dermoid sinus, 249–250
cervical, 249, 249*f*
classification of, 249, 249*t*
defined, 249
differential diagnosis of, 250
imaging of, 249, 250*f*
Dermoid sinus *(Continued)*
nasal, 249, 250*f*
treatment of, 250
Derotational osteotomy, 1034*f*
DES (diethylstilbestrol)
for benign prostatic enlargement, 764*t*
for urinary incontinence, 713, 714*b*, 746*b*
for urinary sphincter leakage, 666*b*
Descemetocele, 286
Descending colon, 468, 468*b*
Desflurane, 127*t*–131*t*
Desmopressin acetate, after hypophysectomy, 599*b*
Detergents
chemical injuries due to, 242
for surgical scrub, 44–46
Detomidine, for premedication, 132*b*
Devocalization, 845–846
complications of, 845
defined, 833
with laryngotomy approach, 845–846, 847*f*
with oral approach, 845, 846*f*
Dewclaw, 260
Dewclaw removal, 260–262
in adults, 260–262, 261*f*
breeds recommended for, 260, 260*b*
in puppies, 260, 261*f*
Dexamethasone (Azium)
for adrenocortical insufficiency, 587*b*
after adrenalectomy, 587*b*
for brachycephalic syndrome, 853
for inflow occlusion, 793*b*
for laryngeal collapse, 857–858
for laryngeal paralysis, 860
for tonsillectomy, 338–339
for tracheal collapse, 871*b*
for upper respiratory surgery, 833
Dexamethasone suppression test, low-dose, 592
Dexmedetomidine, 144, 148*t*–149*t*
for brain surgery, 1342
for premedication, 127*t*–131*t*, 132, 132*b*
Dexmedetomidine-butorphanol-ketamine combination, 150*t*
Dexon (polyglycolic acid) surgical mesh, 68
Dexon (polyglycolic acid) sutures, 62, 63*t*
Dextran 70, 33
Dextrose 5% solution, 31
Diabetes, anesthesia with, 600
Diagnostic peritoneal lavage (DPL), 531, 534, 534*b*, 534*f*
Diagonal leg lifts, as therapeutic exercise, 120, 120*f*
Diaphragm, surgical anatomy of, 920, 921*f*
Diaphragmatic hernia
definition for, 926
peritoneopericardial, 931–933
clinical presentation of, 931–932
definition for, 931
diagnosis of, 931–932
diagnostic imaging of, 932, 932*f*
differential diagnosis of, 932
general considerations and clinically relevant pathophysiology of, 931, 931*b*, 931*f*
medical management of, 932
physical examination findings in, 932

Diaphragmatic hernia *(Continued)*
postoperative care and assessment for, 933
prognosis of, 933
radiographic signs of, 932*b*
surgical technique for, 933
surgical treatment of, 932–933
suture materials and special instruments for, 933
traumatic, 926–931
clinical presentation of, 927
definition for, 926
diagnosis of, 927
diagnostic imaging of, 927, 927*f*
differential diagnosis of, 928
general considerations and clinically relevant pathophysiology of, 926–927
laboratory findings in, 927
medical management of, 928
physical examination findings in, 927
prognosis of, 931
surgical treatment of, 928, 928*b*
anesthesia for, 928, 928*b*, 929*t*–930*t*
complications with, 931
positioning for, 928, 928*b*
postoperative care and assessment for, 930–931
preoperative management of, 928
surgical technique for, 928–930, 930*b*, 931*f*
suture materials and special instruments for, 930
true, 931
Diaphyseal fractures
femoral, 1102–1109
humeral, 1052–1061
radial and ulnar, 1066–1073
tibial and fibular, 1121–1128
Diazepam (Valium)
for extrahepatic biliary surgery, 583*b*
for liver surgery, 540–542
for portosystemic shunts, 555
for premedication, 131
for severe dyspnea, 834*b*
for tracheal collapse, 870
Diazoxide (Proglycem), for insulinomas, 610, 610*b*
Dibenzyline (phenoxybenzamine), to improve urination, 701*t*
DIC (disseminated intravascular coagulation)
with adrenal disease, 594, 594*b*
preoperative management of, with splenic disease, 638, 638*b*
Dicural (difloxacin), 81*t*, 82
Diencephalon, 1323
Diet(s)
for cognitive dysfunction syndrome, 1445–1447
for enteral use, 90–93, 91*t*, 93*t*
liquid (blenderized), 90, 91*t*
monomeric, 90–91, 93*t*
for parenteral nutrition, 92*f*, 93
polymeric, 91–93, 93*t*
Dietary restrictions, preoperative, 36
Diethylstilbestrol (DES)
for benign prostatic enlargement, 764*t*
for urinary incontinence, 713, 714*b*, 746*b*
for urinary sphincter leakage, 666*b*
Diffusion tensor imaging (DTI), 170
Diffusion-weighted imaging (DWI), 170
Difloxacin (Dicural), 81*t*, 82
Digastricus muscle, 1044*f*
Digestive system, 331–511
esophagus in, 365–398
large intestine in, 466–482
oral cavity and oropharynx in, 331–365
perineum, rectum, and anus in, 482–510
small intestine in, 433–466
stomach in, 398–433
Digging, as therapeutic exercise, 121
Digit(s), surgery of, 255–265
biopsy as, 255–257, 256*f*
deep digital flexor tenectomy as, 260, 261*f*
dewclaw removal as, 260–262
in adults, 260–262, 261*f*
breeds recommended for, 260, 260*b*
in puppies, 260, 261*f*
digit amputation as, 262, 262*f*–263*f*
for footpad injuries, 263–265
lacerations as, 263
paw salvage in, 263–265, 264*f*
superficial pad loss as, 263
fusion podoplasty as, 265
onychectomy (declawing) as, 257–260
alternatives to, 257
anesthetic considerations for, 257, 258*t*
defined, 257
dissection, 257*f*, 258–259
distal phalangeal anatomy for, 257*f*
nail clipper, 257*f*, 259
nerve blocks for, 257–258, 259*f*
postoperative care and complications of, 259–260, 260*f*
proper and improper lines of transection in, 257*f*
Digit amputation, 262, 262*f*–263*f*, 1091, 1091*f*
Digital flexor muscles, 1075*f*
Digital pad replacement, 263–265
Digital pad transposition, 263–265
Digital subtraction, 174–175
Digital tumors, digit amputation for, 262, 262*f*–263*f*
Digital video otoscopy, 302
Digoxin (Lanoxin)
for cardiac disease, 789*b*
for gastric dilatation-volvulus, 425*b*
Dihydrotachysterol, for hypocalcemia after thyroidectomy, 624, 624*b*
Dilatation, 419
Dilation, 419
Diltiazem (Cardizem), for cardiac disease, 789*b*
Dioctyl sodium sulfosuccinate (Colace), after prostatic or perineal surgery, 744*b*
Diosmin, for lymphedema, 636
Diphenoxylate with atropine (Lomotil), for tracheal collapse, 871*b*
Direct apposition, for acquired oronasal fistula, 348, 349*f*
Direct bone healing, 1026–1027, 1027*f*–1028*f*
Direct reduction, 989–990, 989*f*–990*f*
with butterfly fragment, 989–990, 991*f*
cerclage wires in, 989–990, 990*f*
for long oblique fractures, 989–990, 990*f*
for transverse long bone fractures, 990
Dirty wounds, 84, 85*t*
infection rate for, 84
prophylactic antibiotics for, 87
Disc disease, thoracolumbar, 1410–1415
complications in, 1414
definitions for, 1410
diagnosis of, 1410–1412, 1412*f*
differential diagnosis of, 1412
general considerations and pathophysiology of, 1410, 1411*f*
medical management of, 1412–1413
postoperative care and assessment in, 1414
prognosis for, 1414–1415
surgical treatment of, 1413, 1413*f*–1414*f*
suture materials and special instruments for, 1414
Disc fenestration, for cervical disc disease, 1379
Disc rupture, acute-on-chronic, 1375
Disc-associated cervical spondylomyelopathy (DA-CSM), 1381
Discoloration, of instruments, 55, 57*t*, 58*b*
Disinfectants, 4, 5*t*
Disinfection, 2, 3*t*
defined, 2*b*, 4
disinfectants used in, 4, 5*t*
level of, 3*t*
high-, 2*b*
low-, 2*b*
terminal, 2*b*
Disk disease
cervical, 1375–1381
complications of, 1380
diagnosis of, 1376–1378
clinical presentation in, 1376
history of, 1376
imaging in, 1376–1377, 1377*f*–1378*f*
laboratory findings in, 1377–1378
physical examination findings in, 1376, 1377*f*
signalment in, 1376
differential diagnosis of, 1378
general considerations and clinically relevant pathophysiology, 1375, 1375*f*–1376*f*
medical management of, 1378–1379
prognosis for, 1381
surgical treatment of, 1379, 1380*f*
chronic degenerative, 1381*t*
Diskography, 1316
Diskospondylitis, 1456–1458
definitions for, 1456
diagnosis of, 1457, 1457*f*
differential diagnosis of, 1457
general considerations and clinically relevant pathophysiology, 1456–1457
medical management of, 1457–1458, 1458*b*

Diskospondylitis *(Continued)*
postoperative care and assessment for, 1458
prognosis for, 1458
surgical technique for, 1458
surgical treatment of, 1458
suture materials/special instruments for, 1458
Dislocation. *see* Luxation(s).
Displaced fractures, 983–984
Dissection onychectomy, 257*f*, 258–259
Disseminated intravascular coagulation (DIC)
with adrenal disease, 594, 594*b*
preoperative management of, with splenic disease, 638, 638*b*
Distal femur
cancellous bone autografts from, 993
comminuted fractures of, 1107–1108
surgical approach to, 1112*f*, 1116
Distal humeral condyle, surgical approach to, 1063, 1064*f*
Distal humerus, osteochondritis dissecans of, 1174*t*, 1186–1188
definitions for, 1186
diagnosis of, 1186–1187, 1187*f*
differential diagnosis of, 1187
general considerations and clinically relevant pathophysiology, 1186
medical management of, 1187
prognosis for, 1188, 1188*b*
surgical treatment of, 1187–1188
Distal physeal fractures
differential diagnosis of, 1115
prognosis for, 1118
surgical treatment of, 1115
anesthesia for, 1115
complications of, 1118
postoperative care and assessment after, 1118, 1118*f*
preoperative management of, 1115
Steinmann pins for, 1117–1118, 1118*f*
surgical anatomy for, 1115
Distal radial fractures, stabilization of, 1075, 1076*b*, 1076*f*
Distal radial osteosarcoma, limb-sparing procedure for, 1305
Distal radial physis
approach to, 1078
elbow subluxation, caused by premature closure of, 1197–1200
definition for, 1197
differential diagnosis of, 1198
general considerations and clinically relevant pathophysiology, 1197–1198, 1197*b*, 1198*f*
medical management of, 1198
prognosis for, 1200
surgical treatment for, 1198
anesthesia for, 1198
complications of, 1200
positioning for, 1198
postoperative care after, 1200, 1200*b*
preoperative management of, 1198
radial lengthening for, 1199
surgical anatomy for, 1198
suture materials and special instruments for, 1199
Distal radial physis *(Continued)*
ulnar-lengthening osteotomy for, 1198–1199, 1199*b*, 1199*f*
ulnar-shortening ostectomy for, 1199, 1199*b*, 1199*f*
surgical approach to, 1132
Distal radius, approaches to, 1075
Distal segmental ulnar osteotomy, 1183
Distal tibia, surgical approach to, 1129
Distal ulna, approaches to, 1075
Distal ulnar fractures, stabilization of, 1075, 1076*b*, 1076*f*
Distal ulnar osteotomy, for medial compartment disease, 1185
Distal ulnar physis
approach to, 1078
elbow subluxation caused by premature closure of, 1197–1200
definition for, 1197
differential diagnosis of, 1198
general considerations and clinically relevant pathophysiology, 1197–1198, 1197*b*, 1198*f*
medical management of, 1198
prognosis for, 1200
surgical treatment for, 1198
anesthesia for, 1198
complications of, 1200
positioning for, 1198
postoperative care after, 1200, 1200*b*
preoperative management of, 1198
radial lengthening for, 1199
surgical anatomy for, 1198
suture materials and special instruments for, 1199
ulnar-lengthening osteotomy for, 1198–1199, 1199*b*, 1199*f*
ulnar-shortening ostectomy for, 1199, 1199*b*, 1199*f*
Distant flaps, 217
Distichia, definition for, 266
Distraction osteogenesis, 1003, 1027–1028, 1029*f*
Distraction-stabilization, for cervical spondylomyelopathy, 1384–1385, 1384*f*
cancellous screws in, 1385, 1385*f*
decompression of spinal cord in, 1386*b*, 1388*f*
full cortical allograft and polyvinylidene spinal plate in, 1385, 1387*f*
intramedullary pins in, 1385, 1386*f*
undercutting of ventral slot in, 1384–1385, 1385*f*
Diuresis, for hypercalcemia, 626, 626*b*
Diuretics
for cardiac disease, 789*b*
for pyometra, 758*b*
Diverticulum(a)
esophageal, 383–385
pulsion, 383
spinal arachnoid, 1394–1396
complications of, 1396
definitions for, 1394
diagnosis of, 1395, 1395*f*
differential diagnosis of, 1395
general considerations and clinically relevant pathophysiology, 1394
medical management of, 1395
Diverticulum(a) *(Continued)*
prognosis of, 1396
surgical treatment of, 1395–1396, 1396*f*
traction, 383
DJD. *see* Degenerative joint disease.
DLSS. *see* Degenerative lumbosacral stenosis.
DLT (double-lumen tube), 135–136, 136*f*
DM (degenerative myelopathy), 1447–1448, 1447*b*
DNA synthesis, inhibition of by antibiotics, 82, 82*b*
Dobutamine (Dobutrex)
for cardiac surgery, 789*b*
for inflow occlusion, 793*b*
for peritonitis, 533, 533*b*
for pheochromocytoma, 595*t*–596*t*
Dobutrex (dobutamine)
for cardiac surgery, 789*b*
for inflow occlusion, 793*b*
Docusate sodium (Colace), after prostatic or perineal surgery, 744*b*
"Dog ears," prevention of, 210, 211*f*
Domino effect, 1388
Donor site, for skin graft, 234
Dopamine
for cardiac disease, 789*b*
for peritonitis, 532–534, 533*b*
for pheochromocytoma, 595*t*–596*t*
Dorsal compression at C1-C2, 1389, 1390*f*
pathophysiology of, 1389–1390
Dorsal laminectomy, 1365
for cauda equina lesions, 1429–1430, 1429*f*
for cervical spondylomyelopathy, 1386, 1389*f*
defined, 1404
of lumbosacral junction, 1433
midcervical, 1372–1373, 1373*f*
of thoracolumbar spine, 1407*f*–1408*f*
Dorsal meatus, 838*f*
Dorsal midcervical laminectomy, 1372–1373, 1373*f*
Dorsal nasal conchae, 838*f*
Dorsal peritoneopericardial mesothelial remnant, 932
Dorsal sagittal sinus, 1343*f*
Dorsal tracheal membrane, 839
Dorsolateral fasciculus (Lissauer's tract), 140
Dorsolateral hemilaminectomy, 1365, 1404
Dostinex (cabergoline)
for pregnancy prevention or termination, 729*b*
for pyometra, 757*b*
Double clamps, for linear external fixation, 1000, 1000*f*
Double ligatures, for hemostasis, 75
Double pelvic osteotomy (DPO), 1212, 1214*b*
Double-contrast cystography, of uroliths, 703, 703*b*
Double-flap repair, for acquired oronasal fistula, 349, 351*f*–352*f*
Double-lumen tube (DLT), 135–136, 136*f*
"Double-spoon" forceps, 162, 162*f*

Double-wrapped peel-back pouches, opening of, 16, 16*f*
Doxycycline (Vibramycin), 81–82, 81*t*
for *Actinomyces* infection, 950*b*
for Lyme disease, 1150, 1150*b*
for reproductive disorders, 726*b*
for rickettsial/ anaplasmal polyarthritis and bacterial L-forms, 1148*b*, 1149
for septic arthritis, 1140*t*
for tracheal collapse, 871*b*
for upper respiratory infection, 838*b*
Doyen intestinal forceps, 54
DPL (diagnostic peritoneal lavage), 531, 534, 534*b*, 534*f*
DPO (double pelvic osteotomy), 1212, 1214*b*
Drain(s), 191–192, 192*b*
active, 191
closed, 191, 191*f*
open, 191*f*
for small spaces, 191–192, 192*f*
for aural hematoma, 320, 320*b*
care for, 192
disadvantages of, 192
passive (Penrose), 191, 191*f*
placement of, 191–192
"strikethrough" with, 192
vented, 191
Drainage, for peritonitis
closed-suction, 534–535, 535*f*
open abdominal, 532, 534–535
Drapes
field (quarter), 39
folding and wrapping of, 13, 15*f*
Draping, 39–40
for abdominal incision, 39, 39*f*
cutting fenestration in, 40*f*
of instrument table, 59
for limb, 40, 40*f*
sterile Backhaus towel clamps in, 39–40, 39*f*
"toweling-in" (additional draping after skin incision) in, 40
Drawer test, 965, 965*f*
Dressing(s). *see* Wound dressing(s).
Dressing room, 19
"Dropped" hocks, 1330
"Drugs of last resort", 82–83
Dry adherent contact layer, 195
Dry-dry dressings, 197*t*–198*t*
Drying, after surgical scrub, 44, 46*f*
DTI (diffusion tensor imaging), 170
Dual echo sequences, 169
Ductility, of needle, 64
Ductus arteriosus, 801, 804
patent. *see* Patent ductus arteriosus.
Ductus deferens, 726–727
Ductus deferopexy, 500
Dulcolax (bisacodyl), for large intestinal and rectal surgery, 467, 467*b*
Duodenum, 436
DuoDerm (hydrocolloid dressing), 197*t*–198*t*, 199
"Dural tail" sign, 1359, 1360*f*
DuraPrep, for sterile skin preparation, 38–39, 38*t*
Duty cycle, of ultrasound beams, 112–113
DWI (diffusion-weighted imaging), 170
Dynamic ulnar osteotomy, 1035*f*
Dyschezia, 466
Dysesthesia, 1427
Dysphagia, cricopharyngeal. *see* Cricopharyngeal achalasia.
Dysplasia, 1134
Dyspnea
preoperative concerns in, 916, 917*f*
sedation for severe, 834*b*

E
Ear
external, 305, 305*f*
flushing of, with ruptured tympanic membrane, 302, 303*b*
glue-ear, 316
healing and, 310
inner, 305, 305*f*
middle, 305, 305*f*
surgical anatomy of, 305, 305*f*–306*f*
Ear canal ablation
total, 308–309, 308*b*, 310*f*–312*f*
vertical, 307–308, 308*f*–309*f*
Ear canal resection, lateral, 306–307, 306*b*, 306*f*–307*f*
Ear cartilage, traumatic lesions of, 323–324
Ear margin, avulsions of, 324, 324*b*, 325*f*. *see also* Ear cartilage, traumatic lesions of.
Ear surgery, 302–330
anesthetic considerations for, 302–303, 303*b*, 303*f*, 304*t*
antibiotics for, 303–305
for aural hematomas, 319–330
bulla osteotomy as
lateral, 309–310, 312*f*
ventral, 310, 313*f*
complications in, 311–312, 313*f*
ear canal ablation as
total, 308–309, 308*b*, 310*f*–312*f*
vertical, 307–308, 308*f*–309*f*
for inflammatory polyps, 327–330
lateral ear canal resection as, 306–307, 306*b*, 306*f*–307*f*
for neoplasia of pinna and external ear canal, 324–327
for otitis externa, 312–316
for otitis media and interna, 316–319
postoperative care and assessment after, 311, 311*b*
preoperative concerns for, 302, 302*b*–303*b*
special age considerations for, 312
suture materials and special instruments for, 310–311
EBBs (endobronchial blockers), 135*b*, 136
Eccentric contraction, 106
Echocardiography
for aortic stenosis, 808–809
for atrial septal defect, 814, 814*b*
for bradycardia, 828
for mitral regurgitation, 799
for patent ductus arteriosus, 802
for pericardial effusion, 819
for pulmonic stenosis, 806
for tetralogy of Fallot, 816
Ectopic cilia, definition for, 266
Ectopic hyperplastic thyroid tissue (EHTT), 624
Ectopic ureter(s), 663–669
bilateral, 664
definitions for, 663
diagnosis of, 664–666
cystoscopy for, 712, 713*f*
history in, 665, 665*b*–666*b*
imaging in, 665–666, 665*f*–666*f*, 666*b*
laboratory findings in, 666
physical examination in, 665
signalment in, 664–665
differential diagnosis of, 666
extraluminal (extramural), 663, 664*f*
general considerations and pathophysiology of, 663–664, 663*f*–664*f*
intraluminal (intramural), 663, 664*f*
medical management of, 666, 666*b*
postoperative care and assessment for, 668, 669*b*
prognosis for, 669
surgical technique for, 667
cystoscopically-guided laser ablation as, 667
neoureterostomy as, 667, 668*f*
ureteroneocystostomy as, 667, 669*f*
surgical treatment of, 666–667, 667*b*
suture materials and special instruments for, 667
Ectropion, 276–281
complications of, 280–281
definition for, 266, 276
diagnosis of, 276–277
clinical presentation in, 276–277
physical examination findings in, 276–277
differential diagnosis of, 278
general considerations and clinically relevant pathophysiology, 276
medical management of, 278
postoperative care and assessment for, 280, 280*b*
prognosis for, 281
surgical techniques for, 278–280
eyelid tacking, 278, 278*f*
modified Hotz-Celsus, 279, 279*f*–280*f*
permanent lateral tarsorrhaphy, 279–280, 280*f*
surgical treatment of, 278
anesthesia for, 278
positioning for, 278
preoperative management of, 278
surgical anatomy for, 278
suture materials and special instruments for, 280
Edema
lymph-. *see* Lymphedema.
pulmonary
due to electrical injury, 241
reexpansion, 887
vaginal. *see* Vaginal prolapse/hyperplasia/tumor.
Edrophonium chloride (Tensilon)
for laryngeal paralysis, 860, 860*b*
for myasthenia gravis, 953, 953*b*
EEA. *see* End-to-end anastomoses.
Egress, in arthroscopy, 158

EHBO. *see* Extrahepatic bile duct obstruction.
Ehrlichia ewingii, polyarthritis due to, 1149
EHTT (ectopic hyperplastic thyroid tissue), 624
Elapidae, 244
Elastic adhesive tapes (Elastikon), for outer layer of bandage, 201
Elasticity, of sutures, 61*b*
Elbow arthrodesis, 1196, 1196*f*, 1197*b*
Elbow dislocation. *see* Elbow luxation, traumatic.
Elbow dysplasia, 1174
  and breeding, 1174*b*
  categorizations and surgical options for, 1174*t*
  considerations for treatment of elbow dysplasia, 1174*b*
  due to incomplete ossification of the humeral condyle, 1174*t*
  due to medial compartment disease, 1174*t*
  due to medial coronoid disease and fragmented coronoid process, 1174–1180, 1174*t*
  due to osteochondritis dissecans, 1174*t*
  due to radial-ulnar incongruence, 1174*t*
  due to ununited anconeal process, 1174*t*
Elbow fold flap, 218, 219*f*
Elbow fractures, 1061–1066
  definitions for, 1061
  differential diagnosis of, 1062
  general considerations and pathophysiology of, 1061, 1061*b*
  lateral or medial, 1064–1065, 1065*f*
    stabilization of, 1064–1065, 1065*f*
  medical management of, 1062
  surgical treatment of, 1062, 1062*b*
    anesthesia for, 1062
    preoperative management of, 1062
    stabilization in
      lateral and medial condylar fractures, 1064–1065, 1065*f*
      T- or Y-fractures, 1065, 1066*f*
    surgical anatomy for, 1062, 1062*b*
    surgical approach to elbow via olecranon osteotomy in, 1063, 1064*f*
  T- or Y, stabilization of, 1065, 1066*f*
Elbow hygroma, 247–248, 247*f*
  treatment of, 247–248, 248*b*
Elbow incongruity, 1197–1200
  definition for, 1197
  differential diagnosis of, 1198
  general considerations and clinically relevant pathophysiology, 1197–1198, 1197*b*, 1198*f*
  medical management of, 1198
  prognosis for, 1200
  surgical treatment for, 1198
    anesthesia for, 1198
    complications of, 1200
    positioning for, 1198
    postoperative care after, 1200, 1200*b*
    preoperative management of, 1198
    radial lengthening for, 1199
    surgical anatomy for, 1198
Elbow incongruity *(Continued)*
    suture materials and special instruments for, 1199
    ulnar-lengthening osteotomy for, 1198–1199, 1199*b*, 1199*f*
    ulnar-shortening ostectomy for, 1199, 1199*b*, 1199*f*
Elbow joint
  arthroscopy of, 166*b*
  palpation of, 962–963, 963*f*
  synovial fluid collection from, 1136*f*
Elbow joint disease, 1174–1202
  canine elbow dysplasia, 1174
  elbow luxation or subluxation as caused by premature closure of the distal ulnar or radial physes, 1197–1200
  congenital, 1200–1202
  traumatic, 1193–1197
Elbow joint incongruity, 1174*t*, 1180–1183
  complications of, 1183
  definition for, 1180
  diagnosis of, 1181–1182
  differential diagnosis of, 1182
  general considerations and clinically relevant pathophysiology of, 1181
  medical management of, 1182
  prognosis of, 1183
  surgical treatment of, 1182–1183, 1183*f*
Elbow joint orientation angle, in frontal plane, 1081
Elbow luxation
  caused by premature closure of the distal ulnar or radial physes, 1197–1200
    definition for, 1197
    differential diagnosis of, 1198
    general considerations and clinically relevant pathophysiology, 1197–1198, 1197*b*, 1198*f*
    medical management of, 1198
    prognosis for, 1200
    surgical treatment for, 1198
      anesthesia for, 1198
      complications of, 1200

      surgical anatomy for, 1198
      suture materials and special instruments for, 1199
      ulnar-lengthening osteotomy for, 1198–1199, 1199*b*, 1199*f*
      ulnar-shortening ostectomy for, 1199, 1199*b*, 1199*f*
  congenital, 1200–1202
    definition for, 1200
    diagnosis of, 1200–1201
    differential diagnosis of, 1201
    general considerations and clinically relevant pathophysiology, 1200, 1200*f*–1201*f*
    medical management for, 1201, 1201*f*
    prognosis for, 1202
    surgical treatment for, 1201–1202, 1201*b*
  traumatic, 1193–1197
    definition for, 1193
Elbow luxation *(Continued)*
    diagnosis of, 1194, 1194*f*
    differential diagnosis of, 1194
    general considerations and clinically relevant pathophysiology, 1193–1194, 1194*b*
    medical management for, 1194, 1195*f*
    prognosis for, 1197
    surgical treatment of, 1194–1195, 1195*b*
      anesthesia for, 1195
      complications of, 1197
      elbow arthrodesis for, 1196, 1196*f*, 1197*b*
      open reduction for, 1195–1196, 1196*f*
      positioning for, 1195
      postoperative care after, 1197
      preoperative management of, 1195
      surgical anatomy for, 1195
      suture materials and special instruments for, 1197
Elbow malformation, congenital. *see* Congenital elbow luxation.
Elbow seroma, 247–248, 247*f*
  treatment of, 247–248, 248*b*
Elbow subluxation
  caused by premature closure of the distal ulnar or radial physes, 1197–1200
    definition for, 1197
    differential diagnosis of, 1198
    general considerations and clinically relevant pathophysiology, 1197–1198, 1197*b*, 1198*f*
    medical management of, 1198
    prognosis for, 1200
    surgical treatment for, 1198
      anesthesia for, 1198
      complications of, 1200
      positioning for, 1198
      postoperative care after, 1200, 1200*b*
      preoperative management of, 1198
      radial lengthening for, 1199
      surgical anatomy for, 1198
      suture materials and special instruments for, 1199
      ulnar-lengthening osteotomy for, 1198–1199, 1199*b*, 1199*f*
      ulnar-shortening ostectomy for, 1199, 1199*b*, 1199*f*
ELD feeding tube, 95–96, 96*f*
Eldepryl (selegiline), for cognitive dysfunction syndrome, 1445–1447
Electrical alternans, 817
  electrocardiogram of, 818, 818*f*
  pathophysiology of, 818, 818*f*
Electrical injuries, 240–241
  treatment of, 241
Electroacupuncture (EA), 155–156, 156*b*
Electrocardiogram
  after cardiac surgery, 798
  of bradycardia, 826*f*–827*f*, 827–828
  of pericardial effusion, 818, 818*f*
Electrocautery, 76
  smoke evacuation system with, 77*b*
Electrocautery snares, for endoscopy, 163
Electrocautery tips, for arthroscopy, 167

Electrodiagnostic procedures, 1316–1320
  brainstem auditory evoked response (BAER), 1318, 1318*f*
  electroencephalography as, 1318, 1318*f*
  electromyography as, 1316–1318, 1316*f*–1317*f*, 1317*t*
  motor nerve conduction velocity as, 1318–1319, 1319*b*, 1319*f*
  repetitive nerve stimulation as, 1319–1320, 1319*f*
  sensory nerve conduction velocity as, 1319
Electroencephalography, 1318, 1318*f*
Electrolyte abnormalities, with renal disease, 650–651, 650*b*
Electromyography (EMG), 1316–1318
  abnormal activity on, 1316, 1317*t*
  complex repetitive discharges on, 1317–1318, 1317*t*
  defined, 1316
  end plate noise or end plate potentials on, 1316, 1316*f*, 1317*t*
  fibrillation potentials on, 1317–1318, 1317*f*, 1317*t*
  insertional activity on, 1317–1318, 1317*t*
  myotonic discharges on, 1317–1318, 1317*t*
  normal silent, 1316*f*
  positive sharp waves on, 1317–1318, 1317*f*, 1317*t*
Electrosurgery, for hemostasis, 76–78
  bipolar, 77–78
  monopolar, 77, 77*b*
    direct contact in, 77
    indirect contact in, 77
  safety with, 77*b*
  smoke evacuation system with, 77*b*
Electrothermal feedback-controlled bipolar vessel sealing system (LigaSure), 78
Elizabethan collar oxygen canopy, 30*t*
Elliptic skin defects, 217, 217*f*
Elongated soft palate, 849–851, 851*f*–852*f*
  resection, 854–855, 855*f*
Embryonal adenomyosarcoma, 673
Embryonic stem cell lines, 968
Embryonic stem cells (ESCs), 968
Emergency sterilization, 4–5
EMG. *see* Electromyography.
Emphysema, subcutaneous, 897–898
Empyema, thoracic. *see* Pyothorax.
En bloc resection
  for cesarean section, 738
  of thoracic wall neoplasia, 913, 914*f*
Enalapril (Vasotec)
  for cardiac disease, 789*b*
  for congestive heart failure, 809*b*
Encephalitis
  necrotizing
    definitions for, 1453
    diagnosis of, 1453–1454, 1454*f*
    differential diagnosis of, 1454
    general considerations and clinically relevant pathophysiology, 1453
    medical management of, 1454–1455, 1455*b*
    prognosis for, 1455
    surgical treatment of, 1455
  pug or pug/Maltese, 1453
  Yorkshire terrier, 1453
Encephalopathy, hepatic, 550, 552, 554–555
End plate noise, in electromyography, 1316, 1316*f*, 1317*t*
End plate potentials, in electromyography, 1316, 1316*f*, 1317*t*
Endobronchial blockers (EBBs), 135*b*, 136
Endochondral bone formation, 958*b*, 1025
Endocrine system, 586–630
  adrenal and pituitary glands in, 586–599
  pancreas in, 599–615
  thyroid and parathyroid glands in, 615–629
Endocrinopathies, infections related to, 84
Endoluminal stent placement, for tracheal collapse, 872–873, 873*b*, 873*f*
Endometrial adenocarcinoma, 751
Endomysium, 1281–1282, 1281*f*
Endoscopic collagen injection, for urinary incontinence, 715, 715*f*
Endoscopically assisted gastropexy, 410, 414*f*
Endoscopy, 158–166
  antibiotics with, 164
  for biopsy, 161*f*
    care after, 166
    of colorectal neoplasia, 476
    equipment for, 161, 164–165
    of gastrointestinal mucosa, 165
    indications for, 159–160
  of choana and nares, 876, 876*f*
  for cytologic studies
    cytologic preparations for, 165
    indication for, 160
    washes for, 165
  defined, 158
  equipment for, 160–163
    care of, 163–164, 164*b*
  flexible
    defined, 158
    equipment for, 160–162, 162*b*, 162*f*
      for biopsy/cytology, 161, 161*f*
      care for, 163–164
      endoscopes as, 160–161, 161*f*
      interventional tools as, 161–162, 162*f*
    indications for, 159–160
    rigid *vs.*, 160*b*
  for foreign body removal
    advantages and disadvantages of, 165*b*
    care after, 166
    esophageal, 378–379
    indications for, 160
    intestinal, 454, 454*b*
    procedure for, 165
  for gastric neoplasia and infiltrative disease, 432
  indications for, 159–160, 159*b*
  of intestinal neoplasia, 457
  patient care after, 166
  procedures of, 164–166
  of pythiosis, 462–463
  rigid
    cannulas for, 158
    defined, 158
    equipment for, 162–163
      care for, 164
    indications for, 160
  for specialized interventional procedures, 166
Endotracheal intubation, through pharyngotomy incision, 1042, 1044*f*
Endotracheal tubes, 135–136, 135*b*, 135*t*
End-tidal carbon dioxide ($EtCO_2$)
  during brain surgery, 1340
  during eyelid surgery, 266–268
End-to-end anastomoses (EEA), of small intestine, 440–447
  definition for, 433
  stapled, 444–447, 444*b*
    inverting end-to-end, 444, 446*f*
    side-to-side or functional, 444–447, 446*f*
    triangulating end-to-end, 444, 445*f*
  sutured, 440–444, 442*f*
    with intestinal segments of disparate size, 440–441, 442*f*
    modified simple continuous pattern for, 441–443, 443*f*
Endure 450, for surgical scrub, 44–46
Enemas, in large intestinal and rectal surgery, 467, 467*b*
Energy needs, nutrition and, 90
Energy-based hemostasis, 76–78, 77*b*, 78*f*
Enostosis, 1295–1296, 1295*b*–1296*b*, 1296*f*
Enoxaparin (Lovenox, Xaparin, Clexane), for pulmonary thromboembolism, 888*b*
Enrofloxacin (Baytril), 81*t*, 82, 82*b*
  after foreign body removal, 166
  for hepatic abscess, 565*b*
  for peritonitis, 531*b*
  for pyometra, 757*b*
  for renal surgery, 653*b*
  for reproductive disorders, 726*b*
  for rickettsial/anaplasmal polyarthritis and bacterial L-forms, 1148*b*
  for upper respiratory infection, 838*b*
Enteral nutrition, 94
  calculation of rate and volume of, 102, 103*b*
  complications of, 103
    gastrointestinal, 103
    mechanical, 103
    metabolic, 103
  defined, 90
  diets for, 90–93, 91*t*, 93*t*
  enterostomy tube for, 101–102, 101*f*–102*f*
  esophagostomy tube for, 95–97
    care and removal of, 95–96
    complications of, 97
    enlarging lateral opening of tubes for, 95–96, 96*f*
    one-step technique for, 96–97, 96*b*
    placement of, 95–96, 97*f*
    using ELD device for, 95–96, 96*f*
  gastrojejunostomy tube for, 102
  gastrostomy tubes for, 97–101
    advantages and disadvantages of, 97
    blind percutaneous, 98, 99*f*
    complications of, 100–101
    flank incision, 98, 100*f*
    low-profile, 100–101
    mid-line laparotomy, 98
    percutaneous endoscopic, 97–98
    replacement of, 100*b*

Enteral nutrition *(Continued)*
nasoesophageal and nasogastric intubation for, 94–95, 94*b*–95*b*, 95*f*
nasojejunal tubes for, 95
pharyngostomy tubes for, 94
tube diameter for, 94, 94*b*
Enteritis
definition for, 462
lymphocytic-plasmacytic, 462
Enterococcus spp., otitis externa due to, 303–305
Enteroenteropexy
definition for, 433
to prevent recurrence of intussusception, 448, 448*b*, 448*f*
Enteropathy, protein-losing, 462
Enteropexy, definition for, 433
Enterostomy, definition for, 433
Enterostomy tube, 101–102, 101*f*–102*f*
Enterotomy
definition for, 433
of small intestine, 438–440, 438*f*–441*f*
Entropion, 276–281
complications of, 280–281
definition for, 266, 276
diagnosis of, 276–277
clinical presentation in, 276–277
physical examination findings in, 276–277
differential diagnosis of, 278
general considerations and clinically relevant pathophysiology, 276
medical management of, 278
postoperative care and assessment for, 280, 280*b*
prognosis for, 281
spastic, 278
surgical techniques for, 278–280
eyelid tacking, 278, 278*f*
modified Hotz-Celsus, 279, 279*f*–280*f*
permanent lateral tarsorrhaphy, 279–280, 280*f*
surgical treatment of, 278
anesthesia for, 278
positioning for, 278
preoperative management of, 278
surgical anatomy for, 278
suture materials and special instruments for, 280
Enucleation, 297–301
definition for, 291
lateral, 299–300, 299*f*
transconjunctival, 298–299, 298*f*
transpalpebral, 300–301, 300*f*
Enzymatic cleaning, of instruments, 56–58
Enzymatic débridement, 185–186
Eosinophilic meningoencephalitis, 1322
Eosinophilic panosteitis, 1295–1296, 1295*b*–1296*b*, 1296*f*
Eosinophilic pleocytosis, 1322
Eosinophils, high, 28*t*
Ephedrine
for cardiac disease, 789*b*
for peritonitis, 533, 533*b*
for urinary incontinence, 713, 714*b*, 746*b*
for urinary sphincter leakage, 666*b*
EPI (exocrine pancreatic insufficiency), 606, 606*b*
Epicardial pacemaker implantation, for bradycardia, surgical treatment of, 829
anesthesia for, 829, 829*b*
electrode placement in, 829, 831*f*
midline celiotomy in, 829
positioning for, 829
postoperative care and assessment in, 830–831
preoperative management of, 829
suture materials and special instruments for, 829–830, 831*f*
technique for, 829, 829*b*
Epidermal growth factor (EGF), 971
Epidermal stem cells, 970
Epidermis, 179
Epididymis, anatomy of, 727, 728*b*
Epidural anesthesia, for orthopedic surgery, 967
Epidural catheter, 154–155, 155*b*
Epidurals, 153–154, 153*t*, 154*b*
Epidurography, 1316
of degenerative lumbosacral stenosis, 1432–1433
Epiglottic retroversion, 863–864
Epiglottis, 839*f*
Epiglottopexy, 863
Epimysium, 1281–1282, 1281*f*
Epinephrine (Adrenaline)
for cardiac disease, 789*b*
for inflow occlusion, 793*b*
for peritonitis, 533*b*
for pheochromocytoma, 595*t*–596*t*
Epiphyseal artery, 1024*f*
Epiphyseal fractures
humeral, 1061
radial and ulnar, 1077–1079
Epiphyseal plate fractures. *see* Physeal fractures.
Episclera, 289, 289*f*
Episioplasty, 740–741, 741*f*
complications of, 745*b*
defined, 720
positioning for, 740–741
Episiotomy, 738–740, 740*f*
complications of, 745*b*
defined, 720
for vaginal leiomyoma, 740*f*
Epitenon, 1283
Epithelial downgrowth, definition for, 284
Epithelial stem cells, 970
Epithelialization, in wound healing, 181, 181*f*
Epitympanic recess, 305, 305*f*
Epulides, 354–356, 356*b*
acanthomatous, 354–356
fibromatous, 354–356, 355*f*
ossifying, 354–356
Equipment room, 19–20
Erosion, gastric, 427–430
definition for, 427
diagnosis of, 428–429
clinical presentation in, 428–429
imaging in, 429
laboratory findings in, 429
physical examination findings in, 429
differential diagnosis of, 429
endoscopic treatment of, 429–430
Erosion, gastric *(Continued)*
general considerations and clinically relevant pathophysiology, 427–428, 428*b*
medical management of, 429, 429*b*
postoperative care and assessment for, 430
prognosis for, 430
surgical technique for, 430
surgical treatment of, 430, 430*b*
anesthesia for, 430
positioning for, 430
preoperative management of, 430
surgical anatomy for, 430
suture materials and special instruments for, 430
Erythromycin, 81–82
for perineal, rectal, or colonic surgery, 467–468, 468*b*
for reproductive disorders, 726*b*
Eschar, 237, 238*f*
Escherichia coli, pyothorax due to, 948*t*, 950*b*
ESCs. *see* Embryonic stem cells.
ESFs. *see* External skeletal fixators.
Esmolol (Brevibloc)
for cardiac disease, 789*b*
for pheochromocytoma, 594–596, 595*t*–596*t*
Esomeprazole (Nexium)
for esophagitis, 366*b*
for NSAID-induced gastrointestinal erosion, 1139*b*
Esophageal cicatrix. *see* Esophageal strictures.
Esophageal dilation balloons, 162
Esophageal disorders
clinical signs of, 365–366, 366*b*
preoperative management of, 366–367, 366*b*
Esophageal diverticula, 383–385
definitions for, 383
diagnosis of, 384
clinical presentation in, 384
imaging in, 384, 384*b*
laboratory findings in, 384
physical examination findings in, 384
differential diagnosis of, 384
general considerations and clinically relevant pathophysiology, 384
postoperative care and assessment for, 385
prognosis for, 385
surgical techniques for, 384–385
surgical treatment for, 384
anesthesia for, 384
positioning for, 384
preoperative management of, 384
surgical anatomy for, 384
Esophageal foreign bodies, 376–380
balloon catheter-assisted removal of, 379, 379*f*
complications of, 380
definition for, 376
diagnosis of, 377–378
clinical presentation in, 377, 377*b*
imaging in, 377–378, 377*f*, 378*b*

Esophageal foreign bodies *(Continued)*
laboratory findings in, 378
physical examination findings in, 377
differential diagnosis of, 378
endoscopic removal of, 378–379
general considerations and clinically relevant pathophysiology, 376–377, 377*b*
postoperative care and assessment for, 380
prognosis for, 380
surgical removal of, 379–380
surgical treatment for, 378
anesthesia for, 378
preoperative management of, 378
surgical anatomy for, 378
suture materials and special instruments for, 380
Esophageal intussusception, 390
Esophageal invagination. *see* Esophageal intussusception.
Esophageal myotomy, tension-relieving, 371–373, 373*f*
Esophageal neoplasia, 385–386
definition for, 385
diagnosis of, 385–386
clinical presentation in, 385
imaging in, 385–386, 385*f*–386*f*
laboratory findings in, 386
physical examination findings in, 385
differential diagnosis of, 386
general considerations and clinically relevant pathophysiology, 385
postoperative care and assessment for, 386
prognosis for, 386
surgical techniques for, 386
surgical treatment for, 386
anesthesia for, 386
preoperative management of, 386
surgical anatomy for, 386
Esophageal stenosis. *see* Esophageal strictures.
Esophageal strictures, 380–383
definition for, 380
diagnosis of, 381
clinical presentation in, 381
imaging in, 381, 381*f*
laboratory findings in, 381
physical examination findings in, 381
differential diagnosis of, 381–382
endoscopic dilation of, 160, 162
general considerations and clinically relevant pathophysiology, 380–381, 380*b*
medical treatment of, 382
postoperative care and assessment of, 383
prognosis for, 383
surgical techniques for, 382–383
balloon dilation, 382–383, 382*b*
bougienage, 382, 382*b*
surgical treatment of, 382
anesthesia for, 382
positioning for, 382
preoperative management of, 382
suture materials and special instruments for, 383
Esophageal surgery, client education and communication for, 375, 376*b*
Esophagectomy, 365
partial, 371–374, 373*f*–375*f*
support or patching techniques after, 374, 376*f*
Esophagitis, treatment of, 366–367, 366*b*
Esophagoscopy, 159*b*
of esophageal strictures, 381, 381*f*
indications for, 366
Esophagostomy, 365, 374
Esophagostomy tube, 95–97
care and removal of, 95–96
complications of, 97
placement of, 95–96, 97*f*
enlarging lateral opening of tubes for, 95–96, 96*f*
one-step technique for, 96–97, 96*b*
using ELD device for, 95–96, 96*f*
Esophagotomy, 365, 370–371, 373*f*
support or patching techniques after, 374, 376*f*
Esophagus, 365–398, 839*f*
anesthetic considerations for, 367–369, 368*t*
antibiotics for, 369
complications in, 375–376
cranial, 393, 393*f*
cricopharyngeal achalasia of, 391–394
definitions for, 365
diverticula of, 383–385
foreign bodies in, 376–380
healing of, 374
hiatal hernia of, 386–390
intussusception of, 390–391
neoplasia of, 385–386
postoperative care and assessment for, 375, 376*b*
preoperative concerns in, 365–367, 365*b*–367*b*
special age considerations for, 376
strictures of, 380–383
surgical anatomy of, 369, 369*b*
surgical approaches to
caudal via caudal lateral thoracotomy, 370, 372*f*
cervical, 369, 370*f*
cranial thoracic via lateral intercostal thoracotomy, 369–370, 371*f*
at heart base via right lateral thoracotomy, 370, 372*f*
surgical techniques for, 369–374, 369*b*
esophagostomy as, 374
esophagotomy as, 370–371, 373*f*
partial esophagectomy as, 371–374, 373*f*–375*f*
support or patching techniques as, 374, 376*f*
suture materials and special instruments in, 375
vascular ring anomalies of, 394–398
Estradiol, in females, 720–721
Estral eversion. *see* Vaginal prolapse/hyperplasia/tumor.
Estral hypertrophy. *see* Vaginal prolapse/hyperplasia/tumor.
Estriol (Incurin), for urinary incontinence, 714*b*, 746*b*
Estrogen
for benign prostatic hyperplasia, 763–764
in males, 722
Estrogen compounds, for pregnancy prevention or termination, 729*b*
Estrumate (cloprostenol)
for pregnancy prevention or termination, 729*b*
for pyometra, 757*b*
Estrus, physical examination during, 720
ESWT (extracorporeal shockwave therapy), 115, 115*b*
Ethibond (polyester) sutures, 62, 63*t*
Ethilon (polyamide) sutures, 62, 63*t*
Ethmoidal artery, 1343*f*
Ethmoidal conchae, 838*f*
Ethmoidal foramina, 1343*f*
Ethyl alcohol, as disinfectant, 5*t*
Ethylene oxide (EtO) sterilization, 5–7
advantages and disadvantages of, 5, 6*t*
effectiveness of, 5–7
environmental and safety hazards with, 5–7
equipment for, 5, 9*f*
failure of, 5–7
strips and bag indicators for, 11*f*
EtO sterilization. *see* Ethylene oxide (EtO) sterilization.
Etodolac (Etogesic), 148*t*–149*t*, 150
Etomidate
for extrahepatic biliary surgery, 583*b*
for induction, 127*t*–131*t*, 134
for liver surgery, 540–542, 541*t*–542*t*
with peritonitis, 533–534
Eunuchoid syndrome, 745
Eustachian tube, surgical anatomy of, 305, 305*f*
Everted laryngeal saccules, 851, 851*f*
resection, 855, 856*f*
Everting sutures, 68
Evisceration
abdominal, 518
defined, 512
definition for, 291
Excellent prognosis, 27, 29*t*
Excision arthroplasty, for scapulohumeral joint luxation, 1164, 1166*f*
Excretions, preoperative, 36
Excretory urography, 665, 665*f*, 666*b*
of bladder rupture, 699*f*
CT-based, 174–175
for urinary incontinence, 712
Exercise, therapeutic. *see* Therapeutic exercise.
Exocrine pancreatic carcinomas, 613–615
definitions for, 613
diagnosis of, 614, 614*b*
differential diagnosis of, 614
general considerations and clinically relevant pathophysiology of, 614, 614*b*
medical management of, 614
prognosis for, 615
surgical treatment of, 614, 615*f*
Exocrine pancreatic insufficiency (EPI), 606, 606*b*

Exocrine pancreatic neoplasia, 613–615
  definitions for, 613
  diagnosis of, 614, 614*b*
  differential diagnosis of, 614
  general considerations and clinically relevant pathophysiology of, 614, 614*b*
  medical management of, 614
  prognosis for, 615
  surgical treatment of, 614, 615*f*
Exophthalmos, definition for, 291
Expectation maximization (EM), 170
Exploratory arthrotomy, for caudal cruciate ligament injury, 1249
Exploratory laparotomy
  for gastrinomas, 613
  for peritonitis, 532, 534
  preoperative management of, 512–513
  technique for, 534
Extensor carpi radialis muscle, 1078*f*
External abdominal oblique muscle, 513*f*, 520, 520*f*, 524*f*, 527*f*
External abdominal oblique muscle flap, 229, 229*f*
External acoustic meatus, 305
External anal sphincter muscle, 484, 727
External auditory canal, 305
  calcification of, 314, 314*f*
  neoplasia of, 324–327
    diagnosis of, 324–325
      clinical presentation in, 324–325
      imaging in, 325, 326*f*
      laboratory findings in, 325
      physical examination findings in, 325, 326*f*
    differential diagnosis of, 325
    general considerations and clinically relevant pathophysiology, 324, 326*f*
    medical management of, 325–327
    postoperative care and assessment for, 327
    prognosis for, 327
    surgical technique for, 327, 327*b*
    surgical treatment for, 327
      anesthesia for, 327
      positioning for, 327
      preoperative management of, 327
      surgical anatomy for, 327
    suture materials and special instruments for, 327
External auditory meatus, 305, 305*f*
External coaptation, 995–997
  casts for, 995–997
    application of, 996–997, 996*b*–997*b*, 996*f*
    indications and biomechanical principles of, 995–996, 996*b*
    postoperative care for, 997, 997*b*, 997*t*
    removal of, 1028
  defined, 958*b*
External connectors, for linear external fixator, 999–1000, 1000*f*
External ear, 305, 305*f*
External ear canal. *see* External auditory canal.
External ethmoidal artery, 1343*f*
External fixation, defined, 958*b*
External fixators, 998–1008
  circular, 1003–1008
    application of, 1004–1007, 1005*b*–1006*b*
      for angular limb deformity correction, 1006–1007, 1007*f*
      for arthrodesis, 1005
      for bone lengthening, 1005–1006, 1006*b*
      for bone transport, 1006, 1006*f*
      for fracture treatment, 1004–1005, 1004*f*
    equipment and supplies for, 1003–1004, 1003*f*
      for frame construction, 1004
      rings as, 1003
      wire fixation bolts as, 1003–1004
      wire tensioner as, 1004, 1004*f*
      wires as, 1003
      wrenches as, 1004
    hybrid, 1008
      application of, 1008, 1009*f*
      equipment and supplies for, 1008
      indications and biomechanical principles of, 1008
      postoperative care for, 1008
    indications and biomechanical principles of, 1003
    postoperative care for, 1007–1008
  linear, 998–1003
    with acrylic splints, 1002
    application of, 1000–1002, 1001*b*
    bilateral-biplanar (type III), 998*f*, 1002
    bilateral-uniplanar (type II), 998*f*, 1001–1002
    equipment and supplies for, 999–1000
      external connectors as, 999–1000, 1000*f*
      fixation pins as, 999, 999*f*
      linkage devices as, 1000, 1000*f*
    indications and biomechanical principles of, 998–999, 998*b*, 998*f*
    with intramedullary pins, 1002
    postoperative care for, 1002–1003
    tie-in, 998*f*
    unilateral-biplanar (type Ib), 998*f*, 1001
    unilateral-uniplanar (type Ia), 998*f*, 1001, 1001*b*
  pancarpal arthrodesis with, 1205
  removal of, 1030
External iliac artery, 527*f*
External inguinal ring, 524, 524*f*
External intercostal muscle, 889
External pudendal artery and vein, 520*f*, 524*f*
External skeletal fixators (ESFs)
  for mandibular and maxillary fractures, 1040–1042, 1041*b*, 1041*f*–1042*f*
  for radial diaphyseal fractures, 1068, 1068*b*
  for tibial diaphyseal fractures, 1123–1124, 1125*f*
External splint, for pectus excavatum, 909, 909*f*
External tension-relieving sutures, 209–210
Extracapsular reconstruction, for cranial cruciate ligament, 1232, 1232*t*, 1236*f*, 1245*t*
  stabilization, lateral, 1235–1237, 1236*f*
  tightrope stabilization as, 1237–1238, 1237*f*
Extracorporeal shockwave therapy (ESWT), 115, 115*b*
Extradural pattern, in myelography, 1315, 1315*f*
Extrahepatic bile duct obstruction (EHBO), due to pancreatic swelling or masses, 604*b*
Extrahepatic biliary ducts, rupture of, 582
Extrahepatic biliary system, 571–585
  bile peritonitis of, 581–584
  cholangiohepatitis of, 571
  cholangitis of, 571
  cholecystitis of, 584–585
  choledocholithiasis of, 571, 578–580
  definitions for, 571
  diagnostic imaging of, 573
  gallbladder mucoceles of, 580–581
  healing of, 576
  prognosis for, 578
  surgical techniques for, 573–576
    bile flow diversion as, 574–576, 575*b*–576*b*, 577*f*
    cholecystectomy as, 571, 574, 574*b*, 575*f*
      laparoscopic, 574, 575*f*
    cholecystoduodenostomy as, 571, 574–575, 577*f*
    cholecystoenterostomy as, 571
    cholecystojejunostomy as, 571, 574–575, 577*f*
    cholecystotomy as, 571, 573, 574*f*
      laparoscopic-assisted, 574
    choledochal tube stenting as, 573
    choledochoduodenostomy as, 571, 574–575, 577*f*
    choledochotomy as, 571, 574, 576*f*
    repair of common bile duct injuries as, 576, 578*f*
  surgical treatment of
    anesthetic considerations in, 571–572
    antibiotics for, 572, 572*b*
    complications in, 578
    postoperative care and assessment in, 577
    preoperative concerns in, 571, 572*b*, 572*f*
    special age considerations in, 578
    surgical anatomy for, 572–573, 572*f*
    suture materials and special instruments for, 576–577
Extrahepatic biliary tract obstruction (EHBO)
  diagnostic imaging of, 573
  preoperative concerns in, 571
  surgical techniques for, 573–576
Extrahepatic portosystemic shunts, 550
  acquired, 550–551
  ameroid constrictors in, 555–556, 555*f*
    placement of, 558, 558*b*
  cellophane banding of, 558
  congenital, 550
  ligation of, 558–559, 559*f*

Extraluminal stents, for tracheal collapse, 871–872, 872*f*
Extraosseous arteries, 1024*f*
Extravesical simple interrupted suture pattern technique, 659, 660*f*
Extremities, bandaging of, 203–204, 205*f*–206*f*
Exudate, of wound healing, 180
Eye
  cherry, 284–286
  healing of, 269
  surgical anatomy of, 268, 269*f*
Eye surgery, 266–301
  anesthetic considerations with, 266–268, 267*t*
  antibiotics for, 268, 268*b*
  complications of, 272
  for conjunctiva and third eyelid, 281–291
  for corneal ulcers, 286–291
  for ectropion, 276–281
  for end-stage glaucoma, 296–301
  for entropion, 276–281
  for eyelid, 266–281
  for eyelid laceration, 272–273
  for eyelid mass, 273–276
  for face and orbit, 291–301
  postoperative care and assessment after, 271, 271*b*
  preoperative concerns for, 266
  special age considerations for, 272
  surgical site preparation for, 266
  suture materials and special instruments for, 269–271, 270*b*, 271*f*
  temporary tarsorrhaphy as, 269, 270*f*
  for traumatic proptosis, 294–296
Eyed needles, 64, 65*f*
Eyelid(s)
  healing of, 269
  surgical anatomy of, 268, 269*f*
Eyelid laceration, 272–273
  complications of, 273
  definition for, 272
  diagnosis of, 272
  differential diagnosis of, 272
  general considerations and clinically relevant pathophysiology, 272, 272*f*
  medical management in, 272
  postoperative care and assessment for, 273
  prognosis for, 273
  surgical techniques for, 272–273, 273*f*
  surgical treatment for, 272
    anesthesia for, 272
    positioning for, 272–273
    preoperative management of, 272
    surgical anatomy for, 272
  suture materials and special instruments in, 273
Eyelid mass, neoplastic, 273–276
  complications of, 276
  diagnosis of, 273–274
    clinical presentation in, 273
    laboratory findings in, 274
    physical examination findings in, 274
  differential diagnosis of, 274
  general considerations and clinically relevant pathophysiology of, 273
  medical management of, 274
Eyelid mass, neoplastic *(Continued)*
  postoperative care and assessment for, 276
  prognosis for, 276
  surgical techniques for, 275–276
    H-plasty pedicle advancement flap, 275, 276*f*
    primary mass removal and closure, 275, 275*b*, 275*f*
    semicircular flap, 275–276, 277*f*
  surgical treatment of, 274
    anesthesia for, 274
    positioning for, 274
    preoperative management of, 274
    surgical anatomy for, 274, 274*f*
  suture materials and special instruments for, 276
Eyelid surgery, 266–281
  anesthetic considerations with, 266–268, 267*t*
  antibiotics for, 268, 268*b*
  complications of, 272
  postoperative care and assessment after, 271, 271*b*
  preoperative concerns for, 266
  special age considerations for, 272
  surgical site preparation for, 266
  suture materials and special instruments for, 269–271, 270*b*, 271*f*
  temporary tarsorrhaphy as, 269, 270*f*
Eyelid tacking, 278, 278*f*

diagnosis of, 1114–1115, 1115*b*
differential diagnosis of, 1115
general considerations and pathophysiology of, 1114, 1114*f*
medical management of, 1115
prognosis for, 1118, 1119*f*
surgical treatment of, 1115
anesthesia for, 1115
complications in, 1118
positioning for, 1115
postoperative care and assessment after, 1118, 1118*f*
preoperative management of, 1115
surgical anatomy for, 1115
surgical technique for, 1115–1118
suture materials and special instruments for, 1118
Femoral head, osteochondritis dissecans (avascular necrosis) of. *see* Legg-Perthes disease.
Femoral head and neck excision, 1213, 1215*f*, 1216, 1217*f*, 1219*t*
Femoral head fractures, 1109–1114
definitions for, 1109
diagnosis of, 1110–1111
differential diagnosis of, 1111
general considerations and pathophysiology of, 1109–1110
medical management of, 1111
Femoral head fractures *(Continued)*
prognosis for, 1114
surgical treatment of, 1111
anesthesia for, 1111
complications in, 1114
positioning for, 1111
postoperative care and assessment after, 1114
preoperative management of, 1111
surgical anatomy for, 1111, 1112*f*
surgical materials and special instruments for, 1113–1114
surgical technique for, 1111–1113
Femoral hernias, 522–527
defined, 522
diagnosis of, 523
differential diagnosis of, 523
general considerations and clinically relevant pathophysiology, 522–523
location of, 522*f*
medical management of, 523
prognosis for, 527
surgical treatment for, 523–527
anatomy in, 524, 524*f*
anesthesia, 523–524
positioning for, 524
postoperative care and assessment in, 527
preoperative management of, 523
suture materials and special instruments for, 527
techniques in, 526–527, 527*f*
Femoral neck fractures, 1109–1114
definitions for, 1109
diagnosis of, 1110–1111
differential diagnosis of, 1111
general considerations and pathophysiology of, 1109–1110
medical management of, 1111
prognosis for, 1114
surgical treatment of, 1111
anesthesia for, 1111
complications in, 1114
positioning for, 1111
postoperative care and assessment after, 1114
preoperative management of, 1111
surgical anatomy for, 1111, 1112*f*
surgical materials and special instruments for, 1113–1114
surgical technique for, 1111–1113
with triangulated K-wires, 1113, 1113*f*
Femoral unicondylar fracture, 1113, 1113*f*
Femoral/sciatic nerve blocks, 153
Femur
osteotomy of, for medial patellar luxation, 1257
palpation of, 965
surgical anatomy of, 1111
Fenestration, 1365
in drapes, 39–40, 40*f*
for thoracolumbar disc disease, 1413–1414, 1413*f*
Fentanyl citrate (Sublimaze), 127*t*–131*t*, 133
for extrahepatic biliary surgery, 583*b*
for inflow occlusion, 793*b*
for pericardiocentesis, 820*b*
Fertilizers, chemical injuries due to, 242

FFP (fresh-frozen plasma), 31, 32*t*, 33
Fiber mesh, 68
FiberLoop repair, 1285–1286, 1286*f*
Fiberoptic headlamp, 21, 21*f*
Fibrillation potentials, in electromyography, 1317–1318, 1317*f*, 1317*t*
Fibrin, in wound healing, 179–180
Fibrin tissue glue (Tisseel), 67, 191
Fibroblasts, in wound healing, 180
Fibrocartilaginous embolic myelopathy (FCE)
  defined, 1448
  hydrated nucleus pulposus extrusion *vs.*, 1452*b*
  pathophysiology of, 1448, 1448*f*
Fibroid degeneration, 1375, 1376*f*
Fibronectins, in wound healing, 179–180, 183
Fibrosarcomas, 1300*t*
  of oral cavity, 354, 355*b*
Fibrosing pleuritis, 924–925, 926*f*
Fibrosis, defined, 1289, 1291
Fibrotic contracture, infraspinatus, 1288–1289
  definitions for, 1288
  diagnosis of, 1288, 1289*f*
  differential diagnosis of, 1288–1289
  general considerations and clinically relevant pathophysiology, 1288
  medical management of, 1289
  postoperative care for, 1289
  prognosis of, 1289
  surgical treatment of, 1289
Fibrous joint(s), 1134
Fibrous joint capsule, 1141, 1141*f*
Fibular fractures, 1121–1133
  diaphyseal, 1121–1128
    definitions for, 1121
    diagnosis of, 1121
    differential diagnosis of, 1121
    general considerations and pathophysiology of, 1121
    medical management of, 1121, 1121*b*
    prognosis for, 1128
    surgical treatment of, 1121–1122, 1121*b*–1122*b*
      anesthesia for, 1122
      bone plates and screws for, 1124, 1124*b*, 1126*f*
      casts for, 1122, 1123*f*
      for comminuted fractures with large butterfly fragment, 1126, 1127*f*
      for comminuted fractures with multiple fragments, 1126, 1127*f*
      complications in, 1128
      craniomedial approach for, 1122, 1122*f*–1123*f*, 1123*b*
      external skeletal fixation for, 1123–1124, 1125*f*
      interlocking nails for, 1123
      intramedullary pins for, 1123, 1124*f*
      for long oblique fractures, 1126, 1127*f*
      positioning for, 1122
      postoperative care and assessment, 1128
      preoperative management of, 1122
Fibular fractures *(Continued)*
      for short oblique fractures, 1124, 1126*f*
      surgical anatomy for, 1122
      surgical technique for, 1122–1126
      suture materials and special instruments for, 1127
      for transverse fractures, 1124, 1126*f*
      type II frames, 1124, 1125*f*
  metaphyseal and articular, 1128–1131
    definitions for, 1128
    diagnosis of, 1128–1129
    differential diagnosis of, 1129
    general considerations and pathophysiology of, 1128
    medical management of, 1129
    prognosis for, 1131
    surgical treatment of, 1129
      anesthesia for, 1129
      complications in, 1131
      positioning for, 1129
      postoperative care and assessment after, 1130
      preoperative management of, 1129
      surgical anatomy for, 1129
      surgical technique for, 1129–1130, 1130*f*
      suture materials and special instruments for, 1130
  physeal, 1131–1133
    definitions for, 1131
    diagnosis of, 1131, 1131*b*
    differential diagnosis of, 1131
    general considerations and pathophysiology of, 1131
    medical management of, 1131
    prognosis for, 1133
    surgical treatment of, 1131–1132, 1131*b*
      anesthesia for, 1132
      for avulsion fractures, 1132, 1132*f*
      for displaced fractures, 1132, 1132*f*
      for nondisplaced fractures, 1132
      positioning for, 1132
      postoperative care and assessment after, 1133
      preoperative management of, 1131
      surgical anatomy for, 1132
      surgical technique for, 1132
      suture materials and special instruments for, 1132
Fibular head advancement, for cranial cruciate ligament rupture, 1243
Field drapes, 39
Figure eights, as therapeutic exercise, 119
Filaroides osleri nodules, 865, 865*f*
Filifactor villosus, pyothorax due to, 949
Filtered back projection, 170
Filum terminale
  surgical anatomy of, 1428
  surgical exposure of, 1429*f*
Finasteride (Proscar), for benign prostatic enlargement, 763–764, 764*t*
Fine needle aspiration biopsy
  of bone neoplasia, 1301, 1302*b*
  of liver, 545
  of lung, 893
  of lymph node, 633
  transrectal, of prostate, 742
Fingernails, in surgical scrub, 44, 45*f*
Finochietto retractors, 54, 54*f*, 796–797, 796*f*
  for thoracotomy, 892*f*
Firocoxib, 148*t*–149*t*
Fistula(e)
  oronasal. *see* Oronasal fistula(e).
  perianal, 501–504
    complications of, 504, 504*b*
    definition for, 501
    diagnosis of, 501–502
      clinical presentation in, 501
      imaging in, 502
      laboratory findings in, 502
      physical examination findings in, 501–502, 502*b*, 502*f*
    general considerations and clinically relevant pathophysiology, 501
    medical management of, 502–503, 502*b*–503*b*
    postoperative care and assessment for, 504
    prognosis for, 504
    surgical technique for, 504
    surgical treatment of, 503–504
      anesthesia for, 504
      positioning for, 504
      preoperative management of, 504
      surgical anatomy for, 504
Fistulae-in-ano. *see* Fistula(e), perianal.
Five-eighths rings, for circular external fixators, 1003
Fixation pins, for linear external fixator, 999, 999*f*
  insertion of, 1000–1001, 1001*b*
Fixation wires, for circular external fixator, 1003
  application of, 1005, 1005*b*
Flagyl. *see* Metronidazole.
Flail chest
  pathophysiology of, 898, 898*f*
  surgical technique for, 899, 900*f*
FLAIR (fluid attenuation inversion recovery) sequences, 169
Flank fold flap, 218, 220*f*
Flank incision gastrostomy tube placement, 98, 100*f*
Flap(s)
  advancement, 218
    for square and rectangular defects, 215, 216*f*
  axial pattern, 222–226, 223*f*
    caudal auricular, 222–223
    caudal superficial epigastric, 224–225, 225*b*, 225*f*
    cranial superficial epigastric, 225
    deep circumflex iliac, 225
    defined, 217, 222
    direct cutaneous vessels used in, 222–223, 223*f*
    genicular, 225
    lateral caudal, 226
    lateral thoracic, 224
    omocervical (superficial cervical), 223–224
    reverse saphenous conduit, 225–226, 226*f*
    superficial brachial, 224

Flap(s) *(Continued)*
superficial temporal artery, 223
thoracodorsal, 224, 224*b*, 224*f*
composite (compound)
defined, 217
muscle, 228–231
caudal sartorius, 230, 230*f*
cranial sartorius, 229–230, 230*f*
external abdominal oblique, 229, 229*f*
flexor carpi ulnaris, 230–231, 231*f*
temporalis, 231, 232*f*
myocutaneous, 226–228, 226*b*
cutaneous trunci, 227, 227*f*
latissimus dorsi, 227, 227*f*
platysma, 226
trapezius osteo-, 228, 228*f*
conjunctival, 289–290, 290*b*
360-degree, 290, 291*f*
hood, 290, 290*f*
distant, 217
H-plasty pedicle advancement, for eyelid mass, 275, 276*f*
hyperbaric oxygen treatment of, 218
interpolation, 217–218
island, 217
local, 217
omental, 231–232, 233*f*
pedicle, 217–232
tubed, 221–222, 222*f*
pouch and hinge, 218–221, 221*f*
rotational, 218
for square and rectangular defects, 215, 216*f*
for triangular defect, 215, 215*f*
semicircular, for eyelid mass, 275–276, 277*f*
subdermal plexus, 217
third eyelid, 283, 284*f*
transposition, 218
for square and rectangular defects, 215, 216*f*
venous congestion in, 218
Flap transfer
delaying, 217–218
microvascular, 232–237
Flash sterilizer, 4–5
Flexibility, of sutures, 60
Flexible endoscopy
for biopsy of small intestine, 437
for brachycephalic syndrome, 853
defined, 158
equipment for, 160–162, 162*b*, 162*f*
for biopsy/cytology, 161, 161*f*
care for, 163–164
endoscopes as, 160–161, 161*f*
interventional tools as, 161–162, 162*f*
indications for, 159–160
rigid *vs.*, 160*b*
Flexicol (hydrocolloid dressing), 196, 197*t*–198*t*, 199
Flexon (stainless steel wire) sutures, 63*t*, 64
Flexor carpi radialis muscle, 1069*f*
Flexor carpi ulnaris muscle, 1075*f*
Flexor carpi ulnaris muscle flap, 230–231, 231*f*
Flow-by oxygen, 29, 30*f*, 30*t*
^{18}FLT (fluorothymidine) uptake, 171
Fludrocortisone acetate (Florinef), after adrenalectomy, 587*b*
Fluid absorption, of sutures, 61*b*
Fluid accumulation, in or under graft, 234
Fluid administration, for brain surgery, 1338
Fluid attenuation inversion recovery (FLAIR) sequences, 169
Fluid flow, in arthroscopy, 158, 167
Fluid therapy
anesthesia and, 139
indications for, 31, 32*t*
intraoperative, 34
preoperative, 31–34
blood products for, 33–34, 34*b*
colloid solutions for, 32–33, 33*b*
crystalloid solutions for, 31–32, 32*t*
Flumazenil (Romazicon), for premedication, 131
Fluorescein stain, to assess skin viability, 189–190
Fluorodeoxyglucose (FDG) uptake, 171, 171*f*
for osteosarcoma, 178, 178*f*
Fluorofil (polypropylene) sutures, 62, 63*t*
Fluoroquinolones, 82
Fluorothymidine (^{18}FLT) uptake, 171
FMCP (fragmented medial coronoid process), CT of, 173*f*
Foam dressings, 197*t*–198*t*, 199
Foam sponge, 202, 202*f*
Foley catheter, placement of, 685–686, 687*f*–688*f*
Follicular stem cells, 970
Folliculitis, interdigital, 250
treatment of, 250
Food intake, preoperative, 36
Footpad injuries, 263–265
lacerations as, 263
paw salvage in, 263–265, 264*f*
superficial pad loss as, 263
Footwear, for surgical team, 42
Foramen magnum decompression, 1344, 1347*f*
for Chiari-like malformation, 1356, 1357*f*
Foraminotomy, 1365, 1427, 1430
Force, defined, 106
Forceps
bone-holding, 54–55, 55*f*
for colonoscopy, 162, 162*f*
for flexible endoscopy, 161, 161*f*
hemostat, 53–54, 53*f*
for laparoscopy and thoracoscopy, 163
tissue, 52–54, 53*f*
Ford interlocking suture pattern, 70, 70*f*
Forebrain, 1323
Foreign bodies
endoscopic removal of
advantages and disadvantages of, 165*b*
care after, 166
indications for, 160
procedure for, 165
esophageal, 376–380
balloon catheter-assisted removal of, 379, 379*f*
complications of, 380
definition for, 376
diagnosis of, 377–378
Foreign bodies *(Continued)*
clinical presentation in, 377, 377*b*
imaging in, 377–378, 377*f*, 378*b*
laboratory findings in, 378
physical examination findings in, 377
differential diagnosis of, 378
endoscopic removal of, 378–379
general considerations and clinically relevant pathophysiology, 376–377, 377*b*
postoperative care and assessment for, 380
prognosis for, 380
surgical removal of, 379–380
surgical treatment for, 378
anesthesia for, 378
preoperative management of, 378
surgical anatomy for, 378
suture materials and special instruments for, 380
gastric, 416–419
definition for, 416
diagnosis of, 417–418
clinical presentation in, 417
imaging in, 417–418, 418*b*
laboratory findings in, 418
physical examination findings in, 417, 417*b*
differential diagnosis of, 418
general considerations and clinically relevant pathophysiology, 416–417, 416*b*–417*b*, 417*f*
medical management of, 418, 418*b*
postoperative care and assessment for, 419, 419*b*
prognosis for, 419
surgical technique for, 418
surgical treatment of, 418
anesthesia for, 418
positioning for, 418
preoperative management of, 418
surgical anatomy for, 418
suture materials and special instruments for, 418
intestinal, 451–455
complications of, 455
definition for, 451
diagnosis of, 453–454
clinical presentation in, 453
imaging in, 453–454, 453*f*
laboratory findings in, 454
physical examination findings in, 453
differential diagnosis of, 454
endoscopic technique for, 454–455
general considerations and clinically relevant pathophysiology, 451–452, 451*b*, 451*f*–453*f*
linear, 416, 452, 452*b*
medical management of, 454
postoperative care and assessment for, 455
prognosis for, 455
surgical technique for, 455
surgical treatment of, 454
anesthesia for, 454
positioning for, 454

indications and biomechanical principles of, 995–996, 996*b*
postoperative care for, 997, 997*b*, 997*t*
external fixators, 998–1008
circular, 1003–1008
application of, 1004–1007, 1005*b*–1006*b*
equipment and supplies for, 1003–1004, 1003*f*–1004*f*
indications and biomechanical principles of, 1003
postoperative care for, 1007–1008
hybrid circular, 1008
application of, 1008, 1009*f*
equipment and supplies for, 1008
indications and biomechanical principles of, 1008
postoperative care for, 1008
linear, 998–1003
application of, 1000–1002, 1001*b*
equipment and supplies for, 999–1000
indications and biomechanical principles of, 998–999, 998*b*, 998*f*
postoperative care for, 1002–1003
removal of, 1030
implant removal after, 1028–1030
intramedullary, 1008–1016
Fracture fixation systems *(Continued)*
interlocking nails for, 1011–1013
application of, 1012–1013, 1013*b*, 1013*f*
equipment and supplies for, 1012, 1012*f*
indications and biomechanical principles of, 1011–1012, 1012*f*
postoperative care for, 1013
intramedullary pins and Kirschner wires for, 1008–1011
application of, 1010–1011, 1010*b*, 1010*f*–1011*f*
equipment and supplies for, 1009–1010, 1010*f*
indications and biomechanical principles of, 1008–1009, 1009*f*
postoperative care for, 1011
orthopedic wire for, 1013–1015
application of, 1014, 1014*b*, 1015*f*
cerclage and hemicerclage wire in, 1013
equipment and supplies for, 1014
indications and biomechanical principles of, 1013–1014, 1013*f*–1014*f*
postoperative care for, 1015
tension bands for, 1015–1016
application of, 1015–1016, 1016*b*
equipment and supplies for, 1015
indications and biomechanical principles of, 1015, 1015*f*
postoperative care for, 1016
plate and screw, 1016–1023
application of, 1019–1021
for bridging plate, 1022, 1022*f*
for buttress plate, 1022
for compression plate, 1021–1022, 1021*b*–1022*b*, 1021*f*
lag screw in, 1019–1020, 1020*b*, 1020*f*
for locking plate, 1022–1023, 1023*b*
locking screw in, 1021
for neutralization plate, 1022
plate screw in, 1021, 1021*f*
position screw in, 1020–1021
equipment and supplies for, 1017–1019
plates as, 1018–1019, 1018*f*–1019*f*
screws as, 1017–1018, 1017*f*
indications and biomechanical principle of, 1016–1017
postoperative care for, 1023
postoperative radiographic assessment for, 1023
Fracture healing, 1023–1035
bone healing, 1025–1030, 1025*b*
direct, 1026–1027, 1027*f*–1028*f*
indirect, 1025–1026, 1025*f*–1027*f*
inflammatory phase of, 1025
intramembranous, 1027–1028, 1028*f*–1029*f*
physeal, 1028, 1031*f*
trabecular, 1028, 1030*f*
complications in, 1031–1032
delayed union as, 1031
malunion as, 1032, 1033*f*
nonunion as, 1031–1032

Fracture healing *(Continued)*
atrophic, 1032, 1032*f*
hypertrophic, 1031–1032, 1032*f*
vascular, 1031–1032
osteomyelitis as, 1032, 1033*f*
and implant removal, 1028–1030
normal, 1023
vascular supply in, 1023–1025, 1024*f*
Fracture management, 1025–1030, 1025*b*
Fracture reduction, 988–990, 988*f*
closed, 989
definition for, 989
indications for, 989*b*
definition for, 988–989
direct, 989–990, 989*f*–990*f*
with butterfly fragment, 989–990, 991*f*
cerclage wires in, 989–990, 990*f*
for long oblique fractures, 989–990, 990*f*
for transverse long bone fractures, 990
indirect, 990, 991*f*
open, 989
definition for, 989
indications for, 989*b*
limited, 989
Fracture repair
anesthesia for, 976–980, 977*t*–978*t*
method, selection of, 985–987
biologic factors in, 986–987, 987*f*
clinical factors in, 987, 988*f*
mechanical forces in, 985, 986*f*
Fracture stabilization
in acute trauma patient, anesthesia for, 976–980, 978*t*–980*t*
temporary, 981–983
advantages and disadvantages of, 982*b*
Robert Jones bandages for, 981–982, 982*b*, 982*f*
soft padded bandages for, 983
spoon splints for, 982–983, 983*f*
Fracture treatment, circular external fixator for, 1004–1005, 1004*f*
Fracture-associated osteomyelitis, 1309–1310
Fracture-associated sarcoma, 1300*t*
Fractured bones, forces acting on, 985, 985*f*
Fractured coronoid process. *see* Fragmented coronoid process.
Fragment removal, arthroscopy for, 168, 168*f*
Fragmented coronoid process (FCP), 1174–1180, 1174*t*
definition for, 1174
diagnosis of, 1175–1176
clinical presentation in, 1175
differential diagnosis of, 1176
imaging for, 1175–1176
arthroscopy, 1176, 1176*f*
bone scintigraphy for, 1176
CT, 1175–1176, 1176*f*
radiographs for, 1175, 1175*b*
imaging in, 1175–1176, 1175*b*, 1175*f*–1176*f*
laboratory findings in, 1176
physical examination in, 1175
general considerations and clinically relevant pathophysiology, 1174–1175, 1174*b*–1175*b*
Fragmented coronoid process (FCP) *(Continued)*
medical management of, 1176, 1177*b*
prognosis of, 1180
surgical treatment of, 1176–1179
anesthesia for, 1177
arthroscopic treatment of, 1177, 1178*f*–1179*f*
indications for, 1177
instrumentation for, 1177
portal sites and technique for, 1177–1178, 1178*f*
subtotal coronoidectomy in, 1178, 1179*f*
complications of, 1180
open, 1179–1180
postoperative care and assessment after, 1179*t*, 1180
preoperative management of, 1177
suture materials and special instruments for, 1180
Fragmented medial coronoid process (FMCP), CT of, 173*f*
Fragmin. *see* Dalteparin.
Frame construction, for circular external fixation, 1004
Fredet-Ramstedt pyloromyotomy, 405, 406*f*
Free T_4 (FT4), 618–619, 619*b*
Freehand technique, for percutaneous liver biopsy, 545
French needle point, 64, 65*f*
Frenulum, persistent, 775, 776*f*
Frequencies, of ultrasound beams, 112
Fresh frozen plasma (FFP), 31, 32*t*, 33
for disseminated intravascular coagulation, 594, 594*b*, 638*b*
Friction knot, 71–72, 71*f*
Front limb exercises, as therapeutic exercise, 121
Frontal open-mouth projection, 317–318, 317*f*
Frontal plane, 1079
Frontal sinus, 837–838, 838*f*, 1343*f*
Frontosagittal index, 908, 908*b*, 908*f*, 908*t*
Frostbite, 241
partial amputation due to, 264*f*
treatment of, 241
fT4 (free T4), 618–619, 619*b*
Full rings, for circular external fixators, 1003
Full-thickness burns, 238, 238*f*
Full-thickness skin grafts, 234–236, 235*f*
defined, 234
mesh, 236
creation of, 236, 236*f*
drainage of, 236
plug, punch, or seed, 235
sheet, 234–235, 235*f*
strip, 235
Functional end-to-end anastomoses, of small intestine, 444–447, 446*f*
Fundus, 572*f*
Funnel chest. *see* Pectus excavatum.
Furacin (nitrofurazone), for wound healing, 186
Furosemide (Lasix)
for cardiac disease, 789*b*
for Chiari-like malformation, 1356
Furosemide (Lasix) *(Continued)*
for congenital hydrocephalus, 1349, 1349*t*
for congestive heart failure, 809*b*
for electrical injury, 241
for hypercalcemia, 626*b*
for pyometra, 758*b*
Furunculosis
interdigital, 250
treatment of, 250
perianal. *see* Perianal fistulae.
Fusiform skin defects, 217, 217*f*
Fusion podoplasty, 265
Fusobacterium spp., pyothorax due to, 948*t*

G

Gabapentin, 148*t*–149*t*, 151
for brain surgery, 1339–1340, 1339*t*
for cervical spine surgery, 1366
for Chiari-like malformation, 1356
for cognitive dysfunction syndrome, 1445–1447
Gadolinium-diethylenetriaminepentaacetic acid (Gd-DTPA), 169
Gag reflex, 1325–1328, 1328*f*
Gait, 1331–1332
ataxia of, 1331–1332, 1332*b*
brainstem nuclei in, 1331, 1332*f*
paresis in, 1332
two-engine, 1365, 1382
Gait training, treadmill, as neurologic rehabilitation exercises, 122
Galastop (cabergoline)
for pregnancy prevention or termination, 729*b*
for pyometra, 757*b*
Gallbladder, 543*f*, 572, 572*f*
rupture of, 582
Gallbladder mucoceles, 580–581
definitions for, 580
diagnosis of, 580–581, 580*f*
differential diagnosis of, 581
general considerations and clinically relevant pathophysiology of, 580
prognosis for, 581
surgical treatment of, 581
Gallstones, 578
definitions for, 578
diagnosis of, 578–579, 578*b*, 579*f*
differential diagnosis of, 579
general considerations and clinically relevant pathophysiology, 578
medical management of, 579
prognosis of, 580
surgical treatment of, 579
Gambee suture pattern, 69, 69*f*
Gas exchange, after cardiac surgery, 797
Gas sterilization, 5–7
ethylene oxide for, 5–7, 6*t*, 9*f*, 11*f*
Gasoline, chemical injuries due to, 241
Gastrectomy, partial, 398
with gastrojejunostomy (Billroth II), 403, 405*f*
invagination of gastric tissue and, 402–403, 402*b*, 402*f*
Gastric arteries, 400
Gastric bloat. *see* Gastric dilatation-volvulus.

Gastric decompression, for gastric dilatation-volvulus, 423
Gastric dilatation, simple, 419
Gastric dilatation-volvulus (GDV), 419–424
  complications of, 424
  definitions for, 419
  diagnosis of, 420–421
    clinical presentation in, 420
    imaging in, 420–421, 421*b*, 421*f*
    laboratory findings in, 421
    physical examination findings in, 420
  differential diagnosis of, 421, 421*b*
  general considerations and clinically relevant pathophysiology of, 419–420, 419*b*, 420*f*
  medical management of, 421–422, 421*b*, 422*f*
  postoperative care and assessment for, 423–424, 423*b*, 425*b*
  prognosis for, 424
  surgical technique for, 423, 423*b*, 424*f*
  surgical treatment of, 422–423
    anesthesia for, 422–423
    positioning for, 423
    preoperative management of, 422
    surgical anatomy for, 423
Gastric foreign bodies, 416–419
  definition for, 416
  diagnosis of, 417–418
    clinical presentation in, 417
    imaging in, 417–418, 418*b*
    laboratory findings in, 418
    physical examination findings in, 417, 417*b*
  differential diagnosis of, 418
  general considerations and clinically relevant pathophysiology of, 416–417, 416*b*–417*b*, 417*f*
  medical management of, 418, 418*b*
  postoperative care and assessment for, 419, 419*b*
  prognosis for, 419
  surgical technique for, 418
  surgical treatment of, 418
    anesthesia for, 418
    positioning for, 418
    preoperative management of, 418
    surgical anatomy for, 418
  suture materials and special instruments for, 418
Gastric infiltrative disease, 430–433
  definitions for, 430
  diagnosis of, 431–432
    clinical presentation in, 431
    imaging in, 431–432
    laboratory findings in, 432, 432*b*
    physical examination findings in, 431
  differential diagnosis of, 432
  general considerations and clinically relevant pathophysiology of, 430–431, 431*b*, 431*f*
  medical management of, 432
  postoperative care and assessment for, 433
  prognosis for, 433
  surgical technique for, 432–433, 432*f*
  surgical treatment of, 432
    anesthesia for, 432
Gastric infiltrative disease *(Continued)*
    positioning for, 432
    preoperative management of, 432
    surgical anatomy for, 432
  suture materials and special instruments for, 433
Gastric mucosa, multiple polyps of. *see* Chronic antral mucosal hypertrophy.
Gastric mucosal hypertrophy. *see* Chronic antral mucosal hypertrophy.
Gastric neoplasia, 430–433
  definitions for, 430
  diagnosis of, 431–432
    clinical presentation in, 431
    imaging in, 431–432
    laboratory findings in, 432, 432*b*
    physical examination findings in, 431
  differential diagnosis of, 432
  general considerations and clinically relevant pathophysiology of, 430–431, 431*b*, 431*f*
  medical management of, 432
  postoperative care and assessment for, 433
  prognosis for, 433
  surgical technique for, 432–433, 432*f*
  surgical treatment of, 432
    anesthesia for, 432
    positioning for, 432
    preoperative management of, 432
    surgical anatomy for, 432
  suture materials and special instruments for, 433
Gastric outflow obstruction, benign, 425–427
  definitions for, 425, 425*f*
  diagnosis of, 426
    clinical presentation in, 426
    imaging in, 426, 426*b*
    laboratory findings in, 426
    physical examination findings in, 426
  differential diagnosis of, 426
  general considerations and clinically relevant pathophysiology of, 425–426, 425*b*
  medical management of, 426, 426*b*
  postoperative care and assessment for, 427
  prognosis for, 427
  surgical technique for, 427
  surgical treatment of, 426–427, 427*f*
    anesthesia for, 427
    positioning for, 427
    preoperative management of, 426–427
    surgical anatomy for, 427
  suture materials and special instruments for, 427
Gastric polyps, 425
  endoscopic removal of, 160, 427
  multiple. *see* Chronic antral mucosal hypertrophy.
Gastric surgery. *see* Stomach.
Gastric tissue invagination, partial gastrectomy and, 402–403, 402*b*, 402*f*
Gastric torsion. *see* Gastric dilatation-volvulus.
Gastric ulcer, 427
  due to neoplasia, 427*f*, 428
Gastric ulceration/erosion (GUE), 427–430
  definitions for, 427
  diagnosis of, 428–429
    clinical presentation in, 428–429
    imaging in, 429
    laboratory findings in, 429
    physical examination findings in, 429
  differential diagnosis of, 429
  endoscopic treatment of, 429–430
  general considerations and clinically relevant pathophysiology of, 427–428, 428*b*
  medical management of, 429, 429*b*
  postoperative care and assessment for, 430
  prognosis for, 430
  surgical technique for, 430
  surgical treatment of, 430, 430*b*
    anesthesia for, 430
    positioning for, 430
    preoperative management of, 430
    surgical anatomy for, 430
  suture materials and special instruments for, 430
Gastrin, 612
Gastrinomas, 427, 612–613
  definitions for, 612
  diagnosis of, 612
    endoscopy for, 612
    history in, 612
    imaging for, 612
    laboratory findings in, 612
    physical examination findings in, 612
    signalment in, 612
  differential diagnosis for, 613
  general considerations and clinically relevant pathophysiology of, 612
  medical management of, 613, 613*b*
  prognosis of, 613
  surgical treatment for, 613
    positioning for, 613
    postoperative care and assessment after, 613
    preoperative management of, 613
    suture materials and special instruments for, 613
    technique for, 613
Gastrin-secreting tumors, 612
Gastritis, chronic hypertrophic. *see* Chronic antral mucosal hypertrophy.
Gastrocnemius reflex, 1335*f*
Gastrocolopexy, 410
Gastroduodenal artery, 604*f*
Gastroduodenoscopy
  defined, 158
  equipment for, 160–161, 161*f*
  for gastric foreign bodies, 418
  indications for, 159*b*
  for small intestine, 434–435
Gastroduodenostomy, 398
  pylorectomy with (Billroth I), 403, 403*b*, 404*f*
Gastroepiploic arteries, 400
Gastroepiploic vessels, ligation of branches of, 402–403, 402*f*

Gastroesophageal intussusception, 390–391
definition for, 390
diagnosis of, 390
clinical presentation in, 390
imaging in, 390, 391*f*
laboratory findings in, 390
physical examination findings in, 390
differential diagnosis of, 391
general considerations and clinically relevant pathophysiology, 390
postoperative care and assessment for, 391
prognosis for, 391
surgical technique for, 391
surgical treatment of, 391
anesthesia for, 391
positioning for, 391
preoperative management of, 391
surgical anatomy for, 391
Gastroesophageal invagination, 390
Gastrointestinal (GI) mucosa, biopsy of, 165
Gastrointestinal stromal tumors (GIST), 456
Gastrojejunostomy, 398
Gastrojejunostomy tube, 102
Gastropexy, 406–415, 406*b*
after splenectomy, 642*b*
belt-loop, 409–410, 413*f*
circumcostal, 407–408, 408*b*, 409*f*–410*f*
definition for, 398
endoscopically assisted, 410, 414*f*
laparoscopic
prophylactic, 410, 413*f*
single-port, 414
sutured, 410
intracorporeally, 411–414
muscular flap (incisional), 408–409, 409*b*, 411*f*–412*f*
percutaneous gastrostomy tube placement with, 98, 100*f*
prophylactic
laparoscopic-assisted, 410, 413*f*
mini-laparotomy, 414–415, 415*f*
tube, 406–407, 407*b*, 407*f*–408*f*
Gastroscopy, 400–401
Gastrosplenic ligament, 639, 639*f*
Gastrostomy, 398
temporary, 403
Gastrostomy tubes, 97–101
advantages and disadvantages of, 97
complications of, 100–101
flank incision, 98, 100*f*
low-profile, 100–101
mid-line laparotomy, 98
percutaneous endoscopic, 97–98
blind, 98, 99*f*
replacement of, 100*b*
Gastrotomy, 398, 401, 401*f*
Gate control theory, 143
Gd-DTPA (gadolinium-diethylenetriaminepentaacetic acid), 169
GDV. *see* Gastric dilatation-volvulus.
Gelfoam, for hemostasis, 75
Geliperm (hydrogel dressing), 197*t*–198*t*, 198–199
Gelpi retractors, 54, 54*f*
Gender, infections related to, 84
General anesthesia, 125
General proprioception (GP), 1332–1333
General visceral afferent (GVA), 142
Genicular axial pattern flap, 225
Genital surgery. *see* Reproductive surgery.
Genitofemoral nerve, 524*f*
Gentamicin, 82
Gentamicin sulfate (Garamycin), for wound healing, 187
Genu varum, 1254
German shepherds, osteomyelitis of young, 1295–1296, 1295*b*–1296*b*, 1296*f*
GFR (glomerular filtration rate), with hyperthyroidism, 619
GI. *see* Gastrointestinal.
Giant cell tumor, 1300*t*
Girth measurement, 106, 107*f*
Glans penis, 727
Glasgow Composite Pain Scale, 144, 145*f*
Glaucoma, end-stage, 296–301
definition for, 281, 296
diagnosis of, 296–297
clinical presentation in, 296
imaging in, 296
laboratory findings in, 296–297
physical examination findings in, 296
differential diagnosis of, 297
enucleation for, 297–301
lateral, 299–300, 299*f*
transconjunctival, 298–299, 298*f*
transpalpebral, 300–301, 300*f*
evisceration and implant for, 301
general considerations and clinically relevant pathophysiology of, 296
medical management of, 297, 297*b*
surgical techniques for, 297–301
surgical treatment for, 297
anesthesia for, 297
positioning for, 297
preoperative management of, 297
surgical anatomy for, 297
Glenohumeral instability, 1167–1169
definition for, 1167
diagnosis for, 1167–1168, 1167*f*
differential diagnoses for, 1168
general considerations and clinically relevant pathophysiology, 1167
medical management of, 1168
prognosis of, 1169
surgical treatment for, 1168–1169
arthroscopy for, 1168, 1168*f*
open surgery for, 1169
postoperative care and assessment for, 1169
suture materials and special instruments for, 1169
tightrope stabilization for, 1168–1169, 1169*f*
Glenoid cavity, approach to, 1049, 1049*f*
Glide, defined, 105
Glide hole, for lag screw, 1019–1020
Glomerular filtration rate (GFR), with hyperthyroidism, 619
Glossectomy, 331, 339–340, 340*b*, 340*f*
Glossopharyngeal nerve, 1325–1328, 1325*t*, 1328*f*–1329*f*
Glottis, 838–839, 839*f*
Glove(s)
aseptic removal of, 48, 49*f*
defects in, 43, 43*b*
lubricating agents for, 47
surgical, 43
Gloving, 47–48
assisted, 47–48, 49*f*
closed, 47, 47*f*
open, 47, 48*f*
Gloving area, 21, 21*b*
Glucocorticoids, 586, 1140–1141
for adrenocortical insufficiency, 586, 587*b*
gastric ulceration and erosion due to, 428
for hyperparathyroidism, 626
for insulinomas, 610
for osteoarthritis, 1145
for upper respiratory system surgery, 833
Glucose
high, 28*t*
low, 28*t*
D-Glucose polysaccharide (maltodextrin), for wound healing, 187
Glue-ear, 316
Glutaraldehyde
as disinfectant, 5*t*
for sterilization, 10
GLUture (cyanoacrylate tissue adhesives), 66–67, 191
Glycocalyx, 1309
Glycolide/ lactide polymer (Polysorb) sutures, 62, 63*t*
Glycomer 631 (Biosyn) sutures, 62, 63*t*
Glycopeptide telavancin (Vibativ), as drugs of last resort, 82–83
Glycopyrrolate
for eyelid surgery, 266–268
for large intestinal surgery, 467
for premedication, 125, 127*t*–131*t*
Glycopyrrolate response test, 827*b*
Glycyl-L-histidyl-lysine tripeptide-copper complex (Iamin), for wound healing, 187
GnRH (gonadotropin releasing hormone), for vaginal prolapse, 760
Goiter, 617
Goitrous hypothyroidism, defined, 615
Golf tee sign, 1315, 1315*f*
GoLytely (polyethylene glycol electrolyte solution), for large intestinal and rectal surgery, 467, 467*b*
Gonadectomy, early-age, 728, 728*b*
Gonadotropin, in males, 722
Gonadotropin releasing hormone (GnRH), for vaginal prolapse, 760
Goniometer, 107–109, 109*f*, 109*t*
Good prognosis, 27, 29*t*
Gown(s)
folding and wrapping of, 13, 15*f*
surgical, 42–43
Gowning, 46–47, 47*f*
Gowning and gloving area, 21, 21*b*
GP (general proprioception), 1332–1333
Gracilis contracture, 1291
Gracilis muscle, 520*f*, 686*f*
Gracilis myopathy, 1291, 1292*f*

Graft(s)
biologic tissue, 68
bone. *see* Bone grafting.
skin. *see* Skin grafts.
Graft bed, 233
Graft "take", 233
Granny knot, 71, 71*f*
Granulation tissue, in wound healing, 180, 181*f*
Granulex, for débridement, 185–186
Granuloma, 194
interdigital, 250
treatment of, 250
lick (acropruritic), 248–249, 248*f*
treatment of, 249
Granulomatous meningoencephalomyelitis, 1453
definitions for, 1453
diagnosis of, 1453–1454, 1454*f*
differential diagnosis of, 1454
general considerations and clinically relevant pathophysiology, 1453
medical management of, 1454–1455, 1455*b*
prognosis for, 1455
surgical treatment of, 1455
Grapiprant, 148*t*–149*t*, 150–151
Grasping forceps, for arthroscopy, 167, 167*f*
Graves disease, 617
Gravity displacement sterilizer, 4–5, 7*f*
exposure periods for, 4, 7*t*
Gray stain, on instruments, 58*t*
Grayscale numbers, 170
Great coronary vein, 800*f*
Greater trochanter
palpation of, 965, 965*f*
translocation of, 1225, 1225*f*
Greenbottle fly larvae, for débridement, 186
Greenstick fractures, 958*b*, 983–984
Growth deformities
defined, 1079
radial and ulnar, 1079–1084
definitions for, 1079
diagnosis of, 1080, 1080*b*
differential diagnosis of, 1080
general considerations and pathophysiology, 1080
medical management of, 1080
prognosis for, 1084
surgical treatment of, 1080–1081, 1081*b*
anesthesia for, 1081
complications of, 1084
oblique osteotomy for, 1082–1083, 1083*f*
ostectomy and autogenous fat graft for, 1081–1082, 1082*f*
ostectomy and free autogenous fat graft for, 1082, 1082*f*
partial physeal resection for, 1082, 1082*f*
positioning for, 1081
postoperative care and assessment after, 1083, 1083*b*
preoperative management of, 1081
preoperative planning for, 1081
surgical anatomy for, 1081
suture materials and special instruments for, 1083
Growth factors, for wound healing, 179, 180*b*, 188
Guarded prognosis, 27, 29*t*
GUE. *see* Gastric ulceration/erosion.
"Guillotine" method, for biopsy of hepatic margin, 546, 547*f*

H

HAC. *see* Hyperadrenocorticism.
Hair coverings, of surgical team, 42
Hair removal, preoperative, 36–37, 37*f*
Half-hitch knot, 71, 71*f*
Hall air drill and assorted bits, 54–55, 56*f*
Halothane, with hepatic dysfunction, 542
Halsted suture pattern, 69
Hamstring contracture, 1291
Hand antisepsis, surgical. *see* Surgical scrub.
Hand instrumentation, for arthroscopy, 167, 167*f*
Hand ties, 72, 73*f*–75*f*
Hand-held retractors, 54, 54*f*
Handle, of flexible endoscope, 158, 160–161, 161*f*
Hanging-leg preparation, 40, 40*f*
Hansen classification, of disk degeneration
cervical, 1375, 1375*f*–1376*f*
thoracolumbar, 1410
Hard palate defects, closure of, 344–345, 344*f*–346*f*, 345*b*
Harelip, 342
Haversian remodeling
in direct bone healing, 1026, 1027*f*
in indirect bone healing, 1025–1026, 1026*f*
HCG (human chorionic gonadotropin), for vaginal prolapse, 760
Head
bandaging of, 203, 203*f*
standing palpation of, 960
Head tilt, 1328–1330, 1330*f*
Head turn, 1328–1330, 1330*f*
Headlamp, fiberoptic, 21, 21*f*
Healing
bone, 1025–1030, 1025*b*
direct, 1026–1027, 1027*f*–1028*f*
indirect, 1025–1026, 1025*f*–1027*f*
inflammatory phase of, 1025
intramembranous, 1027–1028, 1028*f*–1029*f*
physeal, 1028, 1031*f*
trabecular, 1028, 1030*f*
fracture, 1023–1035
complications in, 1031–1032
delayed union as, 1031
malunion as, 1032, 1033*f*
nonunion as, 1031–1032
osteomyelitis as, 1032, 1033*f*
and implant removal, 1028–1030
normal, 1023
vascular supply in, 1023–1025, 1024*f*
wound, 179–183
complications, 194
external factors affecting, 183
growth factors in, 179, 180*b*
host factors affecting, 182
moist, 182
phases of, 179–182
débridement, 180
Healing *(Continued)*
inflammatory, 179–180, 180*b*
maturation, 181–182
repair, 180–181
primary, 193
by secondary intention, 193–194
wound characteristics affecting, 182–183
Hearing, evaluation of, 1325
Heart, surgical anatomy of, 794–795, 794*f*
Heart base tumors, 823
Heart rate, normal, 917*t*
Heart surgery. *see* Cardiac surgery.
Heineke-Mikulicz pyloroplasty, 405, 406*f*
Helicobacter pylori, gastric adenocarcinoma and, 430–431
Helix, 305, 306*f*
Hemangioendothelioma. *see also* Hemangiosarcomas.
malignant cardiac, 823
renal, 675*f*
Hemangiomas, splenic, 645–648
defined, 645
diagnosis of, 646–647, 647*b*
differential diagnosis of, 645*b*, 647, 647*b*
general considerations and pathophysiology of, 645–646
medical management of, 647
postoperative care after, 648, 648*b*
prognosis of, 648
surgical technique of, 648, 648*b*
surgical treatment of, 647–648
suture materials and special instruments for, 648
Hemangiosarcomas (HSAs), 1300*t*
cardiac
diagnosis of, 823–824, 824*f*
pathophysiology of, 823
right atrial, 825, 825*f*
surgical treatment of, 824
prostatic, 771
splenic, 645–648
defined, 645
diagnosis of, 646–647, 647*b*
differential diagnosis of, 645*b*, 647, 647*b*
general considerations and pathophysiology of, 645–646, 645*f*
medical management of, 647
postoperative care after, 648, 648*b*
prognosis of, 648
surgical technique of, 648, 648*b*
surgical treatment of, 647–648
suture materials and special instruments for, 648
Hematochezia, 466
Hematomas
aural, 319–330
definition for, 319
diagnosis of, 320
clinical presentation in, 320
imaging in, 320
laboratory findings in, 320
physical examination findings in, 320
differential diagnosis of, 320
general considerations and clinically relevant pathophysiology of, 319–320

Hematomas *(Continued)*
medical management of, 320, 320*b*
postoperative care and assessment for, 322, 322*b*–323*b*, 322*f*–323*f*
prognosis for, 322–323
surgical techniques for, 321–322, 321*f*
surgical treatment of, 320
anesthesia for, 320
positioning for, 320
preoperative management of, 320
surgical anatomy for, 320
due to pressure sore, 246
in or under graft, 234
splenic, 645–648
defined, 645
diagnosis of, 646–647, 647*b*
differential diagnosis of, 645*b*, 647, 647*b*
general considerations and pathophysiology of, 645–646, 646*f*
medical management of, 647
postoperative care after, 648, 648*b*
prognosis of, 648
surgical technique of, 648, 648*b*
surgical treatment of, 647–648
suture materials and special instruments for, 648
Hematometra, 752
Hematuria, 720
Hemcon Patch (chitosan dressings), 200
Hemicerclage wire, 958*b*, 1013
Hemilaminectomy, 1365
defined, 1404
dorsal, 1365
dorsolateral, 1404
Hemimandible, 1044*f*
Hemiparesis, 1365
Hemipelvectomy, 1303, 1303*f*
Hemiplegia, 1365
Hemivertebra, 1415–1420
complications in, 1420
definitions for, 1415, 1416*f*
diagnosis of, 1415–1417, 1417*f*
differential diagnosis of, 1417
general considerations and pathophysiology of, 1415
medical management of, 1417
postoperative care and assessment in, 1420
prognosis for, 1420
surgical treatment of, 1417–1418, 1418*f*–1419*f*
suture materials and special instruments for, 1420
Hemiwalking, 1332, 1334*f*
Hemoabdomen. *see* Hemoperitoneum.
Hemobilia, 571
Hemocholecyst, 571
Hemoclips, 67
HemoCon (chitosan), for wound healing, 188, 197*t*–198*t*
Hemolymphatic system. *see* Lymphatic system; Spleen.
Hemoperitoneum, 535–538
definitions for, 535
diagnosis for, 536–537, 537*b*, 537*f*
differential diagnosis of, 537
Hemoperitoneum *(Continued)*
general considerations and clinically relevant pathophysiology, 535–536
medical management of, 538
prognosis for, 538
surgical treatment of, 538
anesthesia for, 538
postoperative care and assessment after, 538
preoperative management of, 538
suture materials and special instruments for, 538
Hemorrhage
intraparenchymal, 1362–1363, 1363*f*
in wound healing, 179
Hemorrhagic infarcts, 1448, 1450, 1450*t*, 1451*f*
Hemostasis, 74–78
carbon dioxide (CO_2) laser for, 78
double ligatures for, 75
electrosurgical, 76–78
bipolar, 77–78
monopolar, 77, 77*b*
smoke evacuation with, 77*b*
electrothermal bipolar vessel sealing system for, 78
radiosurgery for, 77–78
topical agents for, 75–76
transfixation ligatures for, 75, 77*f*
Hemostat forceps, 53–54, 53*f*
Heparin
for disseminated intravascular coagulation, 638*b*
fractionated, for pulmonary thromboembolism, 888*b*
low molecular weight
for disseminated intravascular coagulation, 594
for peritonitis, 531, 531*b*
unfractionated
after adrenalectomy, 587*b*
for disseminated intravascular coagulation, 594, 594*b*
for pulmonary thromboembolism, 888*b*
Heparin-activated plasma
for disseminated intravascular coagulation, 594, 594*b*, 638*b*
for peritonitis, 531*b*
Hepatectomy
definition for, 540
partial, 540
for hepatic arteriovenous fistula, 562
total, 540
Hepatic abscess
defined, 563
diagnosis of, 564
differential diagnosis of, 564
general considerations and clinically relevant pathophysiology of, 563–564
medical management of, 564–565, 565*b*
prognosis for, 565–566
surgical treatment for, 565
postoperative care and assessment for, 568
suture materials and special instruments for, 568
Hepatic arteriovenous fistula
general considerations and clinically relevant pathophysiology of, 551, 551*f*
history of, 552, 552*b*
partial hepatectomy for removal of, 562
physical examination findings in, 552
prognosis for, 563
signalment for, 552
Hepatic artery, 603, 604*f*
Hepatic biopsy. *see* Liver biopsy.
Hepatic carcinoids, 566
Hepatic cysts
defined, 563
diagnosis of, 564, 564*b*, 564*f*
differential diagnosis of, 564
general considerations and clinically relevant pathophysiology, 563–564
prognosis for, 565–566
surgical treatment for, 565
Hepatic disease, focal *vs*. diffuse, 544
Hepatic ducts, 572, 572*f*
Hepatic encephalopathy, 550, 552, 554–555
Hepatic function tests, with portosystemic shunt, 554
Hepatic insufficiency, 550
Hepatic lobe torsion, 568–569
Hepatic lobes, 543, 543*f*
Hepatic microvascular dysplasia (HMD)
defined, 550
general considerations and clinically relevant pathophysiology, 551
history of, 552, 552*b*
physical examination findings in, 552
Hepatic necrosis, due to peritonitis, 533
Hepatic oxygenation, with liver surgery, 542
Hepatic surgery. *see* Liver surgery.
Hepatic vein, 543
Hepatobiliary neoplasia, 566–568
diagnosis of, 566–567, 566*b*–567*b*, 567*f*
differential diagnosis of, 567
general considerations and clinically relevant pathophysiology, 566, 566*b*
interventional oncologic treatment for, 567
medical management of, 567
prognosis of, 568
surgical treatment of, 567–568
Hepatobiliary scintigraphy, 573
Hepatocellular adenoma, 566
Hepatocellular carcinoma, 566
Hepatocellular tumors, 566
Hepatoduodenal ligament, 543*f*
Hepatoid tumors, 489
Hepatoma, 566

postoperative care and assessment for, 390
prognosis for, 390
sliding or axial hiatal, 387, 388*f*
surgical technique for, 389, 389*f*
surgical treatment of, 387–389
anesthesia for, 388–389
positioning for, 389
preoperative management of, 388
surgical anatomy for, 389
types of, 387, 388*f*
High-five salute, as therapeutic exercise, 121
High-velocity forces, in fractures, 983–984
Hind limb exercises, as therapeutic exercise, 120–121
Hind limbs
orthopedic examination of, 959–960
recumbent palpation of, 963–964, 964*f*
standing palpation of, 960–961
Hinge flaps, 218–221
Hinges, for circular external fixators, 1004
Hip dysplasia, 1209–1220
definitions for, 1209
diagnosis of, 1209–1211
arthroscopy in, 1211, 1211*f*
clinical presentation in, 1209, 1209*b*
differential diagnosis of, 1211
imaging in, 1210–1211, 1210*b*, 1210*f*
laboratory findings in, 1211
medical management of, 1211–1212
NSAIDs in, 1212*b*
physical rehabilitation in, 1211*b*
rest in, 1211, 1211*b*
weight management in, 1212, 1212*b*
physical examination in, 1144, 1209, 1210*f*
general considerations and clinically relevant pathophysiology, 1209, 1209*b*
surgical treatment for, 1212–1215
anesthesia for, 1214
complications of, 1217–1219
femoral head and neck excision (FHO), 1213, 1215*f*, 1216, 1217*f*, 1219*t*
juvenile pubic symphysiodesis, 1212, 1215, 1215*f*
pelvic osteotomy for, 1212, 1215–1216, 1216*b*, 1216*f*
positioning for, 1214–1215
postoperative care after, 1216–1217
preoperative management of, 1214
surgical anatomy for, 1214, 1214*b*
suture materials and special instruments for, 1216
total hip replacement for, 1212, 1213*f*–1214*f*, 1218*t*
implant designs for, 1212–1213, 1213*f*
Hip joint
arthroscopy of, 166*b*
exploration of, 1223, 1223*b*
osteoarthritis of, physical rehabilitation for, 1211
surgical anatomy of, 1100
Hip joint capsule, reconstruction of, 1223, 1223*b*, 1224*f*
Hip joint disease, 1209–1227
coxofemoral luxation as, 1220–1225
hip dysplasia as, 1209–1220
Legg-Perthes disease, 1225–1227, 1226*f*
Hip joint reconstruction, 1224, 1224*f*
Hip laxity, 966*f*
Hip luxation, 965, 965*f*, 1220–1225
closed reduction of
caudoventral luxation, 1222, 1222*f*
craniodorsal luxation, 1221, 1222*f*
definition for, 1209, 1220
diagnosis of, 1220
clinical presentation in, 1220
differential diagnosis of, 1221
imaging in, 1220, 1221*f*
laboratory findings in, 1220

Hip luxation *(Continued)*
physical examination in, 1220, 1220*f*–1221*f*
general considerations and clinically relevant pathophysiology, 1220, 1220*b*
medical management for, 1221–1222
closed reduction of a caudoventral luxation in, 1222, 1222*f*
closed reduction of a craniodorsal luxation, 1221, 1222*f*
Ehmer slings in, 1221–1222, 1222*f*
hind limb hobbles in, 1222, 1223*f*
prognosis for, 1225
surgical treatment for, 1223
anesthesia for, 1223
capsule reconstruction in, 1223, 1223*b*, 1224*f*
exploration of the hip joint in, 1223, 1223*b*
joint reconstruction in, 1224, 1224*f*
positioning for, 1223
postoperative care after, 1225
preoperative management of, 1223
surgical anatomy for, 1223
translocation of the greater trochanter in, 1225, 1225*f*
Hip replacement, total, 1212, 1213*f*–1214*f*, 1218*t*
implant designs for, 1212–1213, 1213*f*
Hirudiniasis, 204
Hirudo medicinalis, 204
Histiocytic sarcomas, 1308
History taking, 26
HMD (hepatic microvascular dysplasia)
defined, 550
general considerations and clinically relevant pathophysiology, 551
history of, 552, 552*b*
physical examination findings in, 552
HNPE (hydrated nucleus pulposus extrusion), 1375
Hocks
"dropped", 1330
orthopedic examination of, 965*f*
synovial fluid collection from, 1136*f*
Hohmann retractor, 54, 54*f*
Hollow viscous organs, sutures for, 66
Homografts, 232–233
Honey, for wound healing, 187–188, 187*b*
Honey cyst. *see* Salivary mucoceles.
Hood, for surgical team, 42, 43*f*
Hood conjunctival flap, for corneal ulcers, 290, 290*f*
Hopping, 1333–1334, 1333*f*
Horizontal mattress suture pattern, 69, 69*f*
Hospital asepsis
principles of, 1–2, 2*b*
sterile technique for, 2, 2*b*, 3*t*
Hotz-Celsus procedure, for entropion repair, 279, 279*f*
modified, 279, 280*f*
Hounsfield units, 170
Hourglass compression, 1381*t*
Housekeeping supply room, 20
H-plasty, 215
H-plasty pedicle advancement flap, for eyelid mass, 275, 276*f*
HSA (human serum albumin), 32*t*, 33
HSAs. *see* Hemangiosarcomas.
Human chorionic gonadotropin (HCG), for vaginal prolapse, 760
Human serum albumin (HSA), 32*t*, 33
Humeral condylar fractures, 1061–1066
definitions for, 1061
differential diagnosis of, 1062
general considerations and pathophysiology of, 1061, 1061*b*
lateral or medial, 1064–1065, 1065*f*
stabilization of, 1064–1065, 1065*f*
medical management of, 1062
surgical treatment of, 1062, 1062*b*
anesthesia for, 1062
preoperative management of, 1062
stabilization in
lateral and medial condylar fractures, 1064–1065, 1065*f*
T- or Y-fractures, 1065, 1066*f*
surgical anatomy for, 1062, 1062*b*
surgical approach to elbow via olecranon osteotomy in, 1063, 1064*f*
T- or Y, stabilization of, 1065, 1066*f*
Humeral condyle
incomplete ossification of, 1174*t*, 1192–1193
definition for, 1192
diagnosis of, 1192, 1192*f*
differential diagnosis of, 1192
general considerations and clinically relevant pathophysiology, 1192
medical management for, 1192
prognosis for, 1193
surgical treatment of, 1192, 1193*b*, 1193*f*
surgical approach to lateral portion of, 1063, 1064*f*
Humeral diaphysis, surgical approach to, 1054–1055, 1055*f*
Humeral epicondyle, surgical approach to lateral portion of, 1063, 1064*f*
Humeral fractures, 1052–1092
articular, physeal, and metaphyseal, 1061–1066
definitions for, 1061
diagnosis of, 1061–1062
differential diagnosis of, 1062
general considerations and pathophysiology of, 1061, 1061*b*
medical management of, 1062
prognosis for, 1066, 1068*f*
surgical treatment of, 1062, 1062*b*
anesthesia for, 1062
complications of, 1065–1066, 1067*b*
positioning for, 1062
postoperative care and assessment after, 1065, 1067*t*
preoperative management of, 1062
stabilization of lateral and medial condylar fractures in, 1064–1065, 1065*f*
stabilization of proximal epiphyseal and metaphyseal fractures in, 1063–1064
stabilization of proximal physeal fractures in, 1064, 1065*f*
Humeral fractures *(Continued)*
stabilization of T- or Y-fractures of elbow in, 1065, 1066*f*
surgical anatomy for, 1062, 1062*b*
surgical approach to elbow via olecranon osteotomy in, 1063, 1064*f*
surgical approach to lateral portion of humeral condyle and epicondyle in, 1063, 1064*f*
surgical approach to proximal epiphysis in, 1062–1063, 1063*f*
suture materials and special instruments for, 1065
diaphyseal and supracondylar, 1052–1061
comminuted, 1055*f*
with large butterfly fragment (reducible), 1058, 1059*f*
with multiple fragments, 1058–1059, 1060*f*
definitions for, 1052
diagnosis of, 1052–1054
differential diagnosis of, 1054
general considerations and pathophysiology of, 1052
medical management of, 1054
oblique fractures
long, 1058, 1059*f*
short, 1057–1058, 1058*f*
prognosis for, 1061, 1061*f*
surgical treatment of, 1054, 1054*b*
anesthesia for, 1054
bone plates and screws in, 1057, 1057*f*–1058*f*
complications of, 1061
external skeletal fixation in, 1056–1057, 1056*f*–1057*f*
interlocking nail in, 1056, 1056*f*
intramedullary pin in, 1055–1056, 1056*b*, 1056*f*
for midshaft comminuted fractures with multiple fragments, 1058–1059, 1060*f*
for midshaft long oblique fractures or reducible comminuted fractures with large butterfly fragment, 1058, 1059*f*
for midshaft transverse or short oblique fractures, 1057–1058, 1058*f*
postoperative care after, 1059–1061
preoperative management of, 1054
for supracondylar fractures, 1059, 1060*f*
surgical anatomy for, 1054, 1054*b*
surgical approach to, 1054–1055, 1055*f*
suture materials and special instruments for, 1059
transverse, 1057–1058, 1058*f*
Humerus, 1049*f*
palpation of, 963, 963*f*
Humidity, of operating room, 21
Hyaline cartilage, 1141
Hyaluronic acid (HA), for joint disease, 1139

Hybrid circular external fixator, 1008
  application of, 1008, 1009*f*
  equipment and supplies for, 1008
  indications and biomechanical principles of, 1008
  postoperative care for, 1008
Hybrid PET/CT imaging, physics of, 171
Hycodan (hydrocodone bitartrate), for tracheal collapse, 871*b*
Hydralazine (Apresoline), for cardiac disease, 789*b*
Hydrated nucleus pulposus extrusion (HNPE), 1375
  fibrocartilaginous embolic myelopathy *vs.*, 1452*b*
Hydraulic occlusion, of intrahepatic portosystemic shunts, 561
Hydrocephalus, congenital, 1347–1350
  clinical presentation of, 1348
  definition for, 1347
  diagnosis of, 1348
  diagnostic imaging of, 1348, 1348*f*
  differential diagnosis of, 1349
  general considerations and clinically relevant pathophysiology of, 1347–1348
  laboratory findings in, 1348
  medical management of, 1349, 1349*t*
  physical examination findings in, 1348, 1348*f*–1349*f*
  prognosis of, 1350
  surgical treatment of, 1349–1350, 1350*f*
    anesthesia for, 1349
    positioning for, 1349–1350
    postoperative care and assessment after, 1350, 1351*f*–1352*f*
    preoperative management of, 1349
    prognosis of, 1350
    surgical anatomy for, 1349
    surgical technique for, 1350, 1351*f*
    suture materials and special instruments for, 1350
Hydrocodone bitartrate (Hycodan), for tracheal collapse, 871*b*
Hydrocolloid dressings (Flexicol, DuoDerm), 196, 197*t*–198*t*, 199
Hydrocortisone (Solu-Cortef), after hypophysectomy, 599*b*
Hydrocortisone hemisuccinate, for adrenal insufficiency, 587*b*
Hydrocortisone phosphate, for adrenal insufficiency, 587*b*
Hydrodynamic theory, 1347–1348
Hydrofluoric acid, chemical injuries due to, 241
Hydrogel dressing (Hydrosorb, Curafil, Curagel, Intrasite Gel, BioDres, Geliperm, Carravet, Tegagel, Nu-gel, Solugel), 197*t*–198*t*, 198–199
Hydrogen peroxide
  as disinfectant, 5*t*
  as wound cleansers, 189
Hydrogen peroxide plasma sterilization, packaging materials for, 8–9, 9*t*
Hydrolyzed bovine collagen (Woun'Dres Collagen Hydrogel, Collasate), in wound healing, 188
Hydrometra, 752
Hydromorphone, 127*t*–131*t*, 133
  for extrahepatic biliary surgery, 583*b*
  for pericardiocentesis, 820*b*
Hydrophilic contact layers, 195–196, 195*b*
Hydrosorb (hydrogel dressing), 197*t*–198*t*, 198–199
Hydroxyurea, for brain tumors, 1360, 1360*b*
Hygroma
  defined, 247
  due to pressure sore, 246
  elbow, 247–248, 247*f*
    treatment of, 247–248, 248*b*
Hyperadrenocorticism (HAC)
  adrenal-dependent, 586
  anesthesia for, 586–587
  defined, 586
  diagnosis of, 590
  history of, 597
  pituitary-dependent, 586
  preoperative management of, 586
Hyperaldosteronism, medical management of, 593
Hyperalimentation
  defined, 90
  enteral, 94
    calculation of rate and volume of, 102, 103*b*
    complications of, 103
      gastrointestinal, 103
      mechanical, 103
      metabolic, 103
    defined, 90
    diets for, 90–93, 91*t*, 93*t*
    enterostomy tube for, 101–102, 101*f*–102*f*
    esophagostomy tube for, 95–97
      care and removal of, 95–96
      complications of, 97
      enlarging lateral opening of tubes for, 95–96, 96*f*
      one-step technique for, 96–97, 96*b*
      placement of, 95–96, 97*f*
      using ELD device for, 95–96, 96*f*
    gastrojejunostomy tube for, 102
    gastrostomy tubes for, 97–101
      advantages and disadvantages of, 97
      blind percutaneous, 98, 99*f*
      complications of, 100–101
      flank incision, 98, 100*f*
      low-profile, 100–101
      mid-line laparotomy, 98
      percutaneous endoscopic, 97–98
      replacement of, 100*b*
    nasoesophageal and nasogastric intubation for, 94–95, 94*b*–95*b*, 95*f*
    nasojejunal tubes for, 95
    pharyngostomy tubes for, 94
    tube diameter for, 94, 94*b*
  parenteral, 94–102, 94*b*
    complications of, 102–103
    defined, 90
    partial, defined, 90
    total, defined, 90
Hyperammonemia, with portosystemic shunt, 554
Hyperbaric oxygen treatment
  for flaps or grafts, 218
  for open wounds, 189
Hypercalcemia
  diuresis for, 626, 626*b*
  paraneoplastic
    differential diagnosis of, 626*b*
    signs of, 490, 490*b*
    treatment of, 491, 491*b*
Hyperesthesia, 1337, 1337*f*
  Chiari-like malformation with, 1355
  due to cauda equina lesions, 1427
Hyperestrogenism, 773, 773*b*
Hyperkalemia
  atrial standstill due to, 828, 828*b*
  preoperative management of, 678, 679*b*
Hypermetria, definition for, 957
Hyperparathyroidism, 625–627
  definitions for, 625
  diagnosis of, 625–626, 625*b*–626*b*, 625*t*
  general considerations and clinically relevant pathophysiology of, 625
  medical management of, 626
  preoperative management of, 616
  primary, 625
  prognosis for, 627
  surgical treatment of, 626, 626*b*
Hyperplasia
  prostatic, 762–764, 763*t*
    definitions for, 762
    diagnosis of, 762–763, 763*b*
    differential diagnosis of, 763, 763*t*
    general considerations and clinically relevant pathophysiology, 762
    glandular or complex, 762
    key points in, 763*b*
    medical management of, 763–764, 764*t*
    prognosis for, 764
    surgical treatment of, 764
  vaginal, 759–761
    definitions for, 759
    diagnosis of, 759
    differential diagnosis of, 759, 760*f*
    general considerations and clinically relevant pathophysiology, 759, 759*b*
    medical management of, 760
    prognosis for, 761
    surgical treatment of, 760
Hyperthyroidism, 615
  feline, 617–625
    definitions for, 617
    diagnosis of, 618–619
      history in, 618
      imaging of, 618, 618*b*, 618*f*–619*f*
      laboratory findings in, 618–619, 619*b*
      physical examination findings in, 618
      signalment in, 618
    differential diagnosis of, 619
    general considerations and clinically relevant pathophysiology of, 617–618, 618*b*
    medical management of, 619–620, 620*b*
    prognosis of, 624–625, 624*b*
    surgical treatment of, 620–621
      anesthesia for, 621, 622*t*

Hyperthyroidism *(Continued)*
intracapsular thyroidectomy for, 621, 621*b*, 621*f*, 623*f*
intraoperative considerations for, 622*t*
modified extracapsular approach for thyroidectomy in, 623, 623*b*, 623*f*
modified intracapsular approach for thyroidectomy in, 623
positioning for, 621
postoperative care and assessment in, 622*t*, 624, 624*b*, 624*f*
preoperative management of, 620–621, 620*b*, 622*t*
suture materials and special instruments for, 623–624
primary, 615
Hypertonic saline (Curasalt, Curity) dressing, 196–198, 197*t*–198*t*
Hypertonic saline solutions, 32, 32*t*
Hypertrophic nonunion, 1031–1032
Hypertrophic osteodystrophy, 1296–1297, 1296*b*–1297*b*, 1297*f*
Hypertrophic osteopathy, 1297–1298, 1298*f*
Hypertrophic pulmonary osteoarthropathy, 1297–1298, 1298*f*
Hypertrophic pulmonary osteopathy, 1297–1298, 1298*f*
Hypertrophy, vaginal (estral). *see* Vaginal prolapse/hyperplasia/tumor.
Hyphema, 281
Hypoadrenocorticism
anesthesia for, 586–587
preoperative management of, 586
Hypoalbuminemia, 33, 33*b*
in hepatic disease, 540
Hypocalcemia
after parathyroidectomy, 627
after thyroidectomy, 624, 624*b*
Hypochlorite, as disinfectant, 5*t*
Hypodermis, 179
Hypogastric nerve, 689*f*, 726–727, 727*f*
Hypoglossal nerve, 1325–1328, 1325*t*, 1329*f*
Hypoglycemia
due to peritonitis, 530–531
in hepatic disease, 540
Hypokalemia, due to peritonitis, 530–531
Hyponatremia, due to peritonitis, 530–531
Hypoparathyroidism, after thyroidectomy, 620
Hypophysectomy, 597–598, 598*b*
defined, 586
postoperative care after, 599*b*
prognosis after, 599
surgical anatomy for, 599, 599*f*
suture materials and special instruments for, 599
Hypophysis, 597
Hypoplastic trachea, 852–853, 852*b*, 852*f*
Hypoplastic urethra, bladder flap reconstruction of, 716, 716*f*–717*f*
Hypopyon, 281
Hypospadias, 775–777
definition for, 775
diagnosis of, 775, 776*f*
differential diagnosis of, 775
Hypospadias *(Continued)*
general considerations and clinically relevant pathophysiology, 775, 775*b*
medical management of, 775–776
prognosis for, 777
surgical treatment of, 776
anesthesia for, 776
positioning for, 776
postoperative care and assessment in, 776–777
preoperative management of, 776
surgical anatomy for, 776
surgical technique for, 776
prepuce reconstruction as, 776, 777*f*
subtotal penile amputation as, 776, 778*f*
urethral reconstruction as, 776
Hypotension
infections related to, 84
with peritonitis, 532, 533*b*
Hypothalamus, 1324*f*
Hypothyroidism
anesthesia and, 616
antibiotics with, 616
defined, 615
goitrous, 615
nongoitrous, 615
preoperative management of, 615
treatment of, 615*b*
Hypoventilation, after cardiac surgery, 797
Hypovolemia, 31
Hypoxia, 28*t*, 29
Hysterectomy
defined, 720
ovario-. *see* Ovariohysterectomy.
Hysterotomy. *see* Cesarean section.

for hybrid PET/CT, 171
magnetic resonance imaging, 169–170
positron emission tomography, 170–171, 171*f*
Imbrication
of cranial cruciate ligament rupture, 1227
lateral, for medial patellar luxation, 1260–1261, 1261*f*
Imepitoin, for brain surgery, 1339–1340, 1339*t*
Imipenem, 80–81
as drug of last resort, 82–83
Imipramine (Tofranil), for urinary incontinence, 714*b*, 746*b*
Immersible scopes, 158
Immunologic acute reactions, 34
Implanted medical devices, infections related to, 86
Imuran. *see* Azathioprine.
Inanimate sources, of contamination, 1
Incidentalomas, defined, 590
Incision(s), relaxing, 210–211
multiple punctate, 210, 212*f*
simple, 210, 212*f*
V-to-Y plasty, 210, 212*f*
Z-plasty, 210–211, 212*f*
Incisional blocks, for thoracostomy tube placement, 918*b*

Incisional gastropexy, 408–409, 409*b*, 411*f*–412*f*
Incisional hernias, 518
Incisors, 1037*f*
Inclination, angle of, 1209
  of femur, 1111
Incline walking, as therapeutic exercise, 120
Incomplete fractures, 983–984
Incomplete ossification of humeral condyle (IOHC), 1174*t*, 1192–1193
  definition for, 1192
  diagnosis of, 1192, 1192*f*
  differential diagnosis of, 1192
  general considerations and clinically relevant pathophysiology, 1192
  medical management for, 1192
  prognosis for, 1193
  surgical treatment of, 1192, 1193*b*, 1193*f*
Incontinence
  fecal, 507–510
    complications of, 509
    definition for, 507
    diagnosis of, 507–508
      clinical presentation in, 507–508
      imaging in, 508
      laboratory findings in, 508
      physical examination findings in, 508
    differential diagnosis of, 508
    general considerations and clinically relevant pathophysiology, 507, 507*b*
    medical management of, 508, 508*b*
    postoperative care and assessment for, 509
    prognosis for, 509–510
    surgical techniques for, 508–509
      fascial sling, 508–509
      implantation of silicone elastomer, 509, 509*f*
    surgical treatment of, 508
      anesthesia for, 508
      positioning for, 508
      preoperative management of, 508
      surgical anatomy for, 508
  urinary, 712–717
    definitions for, 712
    diagnosis of, 712–713, 713*f*
    differential diagnosis of, 713
    general considerations and pathophysiology of, 712, 712*b*
    medical management of, 713–714, 714*b*
    prognosis for, 717
    surgical technique for, 714–716
      artificial urethral sphincter placement as, 716
      bladder flap reconstruction of hypoplastic urethra as, 716, 716*f*–717*f*
      colposuspension as, 714
      cystourethropexy as, 714–715, 715*f*
      endoscopic collagen injection as, 715, 715*f*
    surgical treatment of, 714, 714*b*
      complications of, 716
      postoperative care after, 716
      suture materials and special instruments for, 716
Incurin (estriol), for urinary incontinence, 714*b*
Incus, 305, 305*f*
Inderal (propranolol)
  for cardiac disease, 789*b*
  for feline hyperthyroidism, 620–621, 620*b*
  for pheochromocytoma, 594–596
Indirect bone healing, 1025–1026, 1025*f*–1027*f*
Indirect guidance method, 545
Indirect reduction, 990, 991*f*
Induced pluripotent stem cells, 968
Induction medication
  etomidate as, 127*t*–131*t*, 134
  ketamine as, 127*t*–131*t*, 134–135
  propofol 28 as, 127*t*–131*t*, 134
  propofol as, 127*t*–131*t*, 133–134
  thiopental as, 127*t*–131*t*, 133
Infected wounds, sutures for, 66
Infection(s)
  in anal sac, 493–496
  definition for, 83
  prostatic, 763*t*
  surgical. *see* Surgical infections.
  surgical site, 36
    risk factors for, 190, 190*b*
Infectious arthritis. *see also* Septic arthritis.
  medical management of, 1139–1140, 1140*t*
Infectious arthropathies, 1134, 1135*b*, 1135*t*
Infectious endophthalmitis, 286
Infectious pericarditis, 817
Infiltrative disease, gastric, 430–433
  definitions for, 430
  diagnosis of, 431–432
    clinical presentation in, 431
    imaging in, 431–432
    laboratory findings in, 432, 432*b*
    physical examination findings in, 431
  differential diagnosis of, 432
  general considerations and clinically relevant pathophysiology, 430–431, 431*b*, 431*f*
  medical management of, 432
  postoperative care and assessment for, 433
  prognosis for, 433
  surgical technique for, 432–433, 432*f*
  surgical treatment of, 432
    anesthesia for, 432
    positioning for, 432
    preoperative management of, 432
    surgical anatomy for, 432
  suture materials and special instruments for, 433
Inflammatory arthropathies, 1134, 1135*b*, 1135*t*
Inflammatory bowel disease (IBD), 462, 477
Inflammatory pain, 140
Inflammatory phase
  of bone healing, 1025
  of wound healing, 179–180, 180*b*
Inflammatory polyps, 327–330
  definition for, 327
  diagnosis of, 328
    clinical presentation in, 328
Inflammatory polyps *(Continued)*
    imaging in, 328, 329*f*
    laboratory findings in, 328
    physical examination findings in, 328, 328*f*
  differential diagnosis of, 328
  general considerations and clinically relevant pathophysiology, 327
  medical management of, 328
  postoperative care and assessment for, 329–330
  prognosis for, 330
  surgical techniques for, 329
  surgical treatment for, 328–329
    anesthesia for, 329
    positioning for, 329
    preoperative management of, 328–329
    surgical anatomy for, 329
  suture materials and special instruments for, 329
Inflammatory synovitis, 1145
Inflow, in arthroscopy, 158
Inflow occlusion
  drugs for, 788–793, 793*b*
  open patch-graft correction with, 807
  surgical technique for, 788, 795, 795*f*–796*f*
Infraspinatus muscle
  fibrotic contracture of, 1288–1289
    definitions for, 1288
    diagnosis of, 1288, 1289*f*
    differential diagnosis of, 1288–1289
    general considerations and clinically relevant pathophysiology, 1288
    medical management of, 1289
    postoperative care for, 1289
    prognosis of, 1289
    surgical treatment of, 1289
  surgical anatomy of, 1049*f*–1050*f*, 1063*f*
Infraspinatus tenotomy, for exposure of the scapulohumeral joint, 1158–1159, 1160*f*–1161*f*
Ingress, in arthroscopy, 158
Ingrown tails, 252, 254*f*
Inguinal canal, 524, 524*f*
Inguinal hernias, 522–527
  caudal abdominal fat pad and, 523*b*
  defined, 522
  diagnosis of, 523
  differential diagnosis of, 523
  general considerations and clinically relevant pathophysiology, 522–523
  location of, 522*f*
  medical management of, 523
  neutering animals with, 523*b*
  surgical treatment for, 523–527
    anatomy in, 524, 524*f*
    anesthesia, 523–524
    positioning for, 524
    postoperative care and assessment in, 527
    preoperative management of, 523
    prognosis for, 527
    suture materials and special instruments for, 527
  techniques for, 524–525, 524*f*–525*f*
Inguinal ligament, 527*f*
Inhalants, 127*t*–131*t*, 135

Inner ear, 305, 305*f*
Inocor (amrinone), for cardiac disease, 789*b*
Inosculation, 233–234
Inotropes, for cardiac disease, 789*b*
Insertion tube, of flexible endoscope, 158, 160–161, 161*f*
Insertional activity, in electromyography, 1317–1318, 1317*t*
Insorb (absorbable skin staples), 67–68
Instrument(s), 50–59
  care and maintenance of, 55–59
    cleaning in, 56–58, 56*b*
    for discoloration, 55, 57*t*, 58*b*
    lubricating and autoclaving in, 58, 58*b*
  categories of, 50–55
    clamps as, 54–55, 55*f*
    curettes as, 54–55
    forceps as
      bone-holding, 54–55, 55*f*
      hemostat, 53–54, 53*f*
      tissue, 52–54, 53*f*
    hall air drill and assorted bits as, 54–55, 56*f*
    for left-handed surgeons, 52*b*
    needle holders as, 50–52, 51*f*
      palmed grip for, 52, 52*f*
      pencil grip for, 52, 52*f*
      thenar grip for, 52–53, 52*f*
      thumb-ring finger grip for, 52, 52*f*
    neurosurgery, 54–55, 57*f*
    orthopedic, 54–55, 56*f*
    osteotomes and chisels as, 54–55, 56*f*
    periosteal elevators as, 54–55, 55*f*
    retractors as, 54, 54*f*
    rongeurs as, 54–55, 55*f*
    scalpels as, 50, 51*f*
    scissors as, 50, 51*f*
    suction tips as, 54–55, 54*f*
  cold sterilization for, 10, 59
  corrosion or pitting of, 55, 57*t*
  packs for, 58
    basic orthopedic, 59*t*
    basic soft-tissue, 58, 58*t*
  sterilization of, 4–10
    handling and storage of, 13–16
    packaging materials for
      based on device type, 11–12, 12*t*
      sterilization method, 8–9, 9*t*
    shelf life after, 13
    unwrapping and opening of, 14
      for large sterile linen/paper/polypropylene packs that cannot be held during distribution, 14
      from sterile container systems, 16, 17*f*
      for sterile items in paper/plastic or plastic peel-back pouches, 16, 16*f*
      for sterile linen/paper packages that can be held during distribution, 14–16, 16*f*
    wrapping materials for, 12, 12*t*
  troubleshooting stain guide for, 56–58, 58*t*
Instrument brushes, 58
Instrument packs, wrapping of, 13, 14*f*
Instrument portal, 158
Instrument table, 22
  draping and organization of, 59
Instrument ties, 72, 72*f*
Insulin , for hyperkalemia, 828*b*
Insulin-like growth factor-1 (IGF-1), 971
Insulinomas, 609–612
  defined, 599–600
  definitions for, 609
  diagnosis of, 609–610
    history in, 609, 609*b*
    imaging in, 609
    laboratory findings in, 610, 610*b*
    physical examination findings in, 609
    signalment in, 609
  differential diagnosis of, 610
  general considerations and clinically relevant pathophysiology, 609, 609*b*
  medical management of, 610
  prognosis for, 611–612, 612*b*
  reported survival times for dogs with, 612*t*
  surgical treatment of, 610–611
    anesthesia for, 610
    complications of, 611
    positioning for, 611
    postoperative care and assessment of, 611, 611*b*
    preoperative management of, 610
    suture materials and special instruments for, 611
    technique for, 611, 611*b*, 611*f*
Integumentary surgery, 179–265
  for animal bite wounds and abscesses, 243–244, 243*f*, 244*b*
  for burns and other thermal injuries, 237–240
  caudectomy as, 253–255
  for dermoid (pilonidal) sinus, 249–250
  of digits and footpads, 255–265
    biopsy as, 255–257, 256*f*
    deep digital flexor tenectomy as, 260, 261*f*
    dewclaw removal as, 260–262
    digit amputation as, 262, 262*f*–263*f*
    for footpad injuries, 263–265
    fusion podoplasty as, 265
    onychectomy (declawing) as, 257–260
  for elbow hygroma, 247–248, 247*f*
  fundamental principles of, 190, 190*b*
  for interdigital pyoderma, 250
  for lick granulomas, 248–249, 248*f*
  plastic and reconstructive. *see* Plastic and reconstructive surgery.
  for pressure sores, 246–247, 246*t*, 247*b*
  for redundant skin folds, 251–253
    of lips, 251
    of nasal, 251–252, 253*f*
    of tail, 252–253, 254*f*
    of vulvar, 252, 254*f*
  risk factors for surgical site infection in, 190, 190*b*
  for skin biopsy, 212–213
  for skin tumors, 213–214, 213*b*–214*b*, 213*f*
  for snakebite, 244–246
  wound management in. *see* Wound management.
Intensity, of ultrasound beams, 112
Interactive dressings, 196
Intercapital ligament, and thoracolumbar disc disease, 1410, 1411*f*
Intercostal blocks, for thoracostomy tube placement, 918*b*
Intercostal nerve, 888–889
Intercostal nerve blocks, 152
Intercostal spaces
  surgical anatomy of, 888–889
  for thoracotomy, 889, 889*t*
Intercostal thoracotomy, for esophageal surgery, 369–370, 371*f*
  caudal, 370, 372*f*
  right, 370, 372*f*
Interdental fixation, for mandibular and maxillary fractures, 1038, 1038*f*
Interdental stabilization techniques, for mandibular and maxillary fractures, 1037–1038
Interdental wires, for mandibular and maxillary fractures, 1038, 1039*f*
Interdigital pyoderma, 250
  treatment of, 250
Interfragmentary wires, 958*b*, 1013
  for mandibular and maxillary fractures, 1038–1040, 1039*t*, 1040*f*
  for mandibular transverse fractures, 1045, 1046*f*
Interlocking nails
  for femoral fractures, 1105, 1105*f*, 1106*b*
  for humeral diaphyseal fractures, 1056, 1056*f*
  for intramedullary fixation, 1011–1013
    application of, 1012–1013, 1013*b*, 1013*f*
    equipment and supplies for, 1012, 1012*f*
    indications and biomechanical principles of, 1011–1012, 1012*f*
    postoperative care for, 1013
  for tibial diaphyseal fractures, 1123
Intermediate layer, of wound dressing, 200–201
Intermeniscal ligament, 1234*f*
Internal abdominal oblique muscle, 513*f*, 520, 520*f*, 524*f*, 527*f*
Internal anal sphincter muscle, 484
Internal fixation, 958*b*. *see also* Intramedullary (IM) fixation; Plate and screw fixation.
Internal inguinal ring, 524, 524*f*
Internal intercostal muscle, 889
Internal obturator transposition herniorrhaphy, 500, 500*f*
Internal pudendal artery, 689*f*, 727*f*
International normalized ratio (INR), 888*b*
Interpolation flaps, 217–218
Interrupted suture patterns, 68–69
  cruciate, 69, 69*f*
  Gambee, 69, 69*f*
  Halsted, 69
  horizontal mattress, 69, 69*f*
  simple, 68–69, 69*f*
  vertical mattress, 69, 69*f*
Interstitial cell tumors, of scrotum, 773
Intertragic incisure, 305, 306*f*

Intertriginous dermatitis, due to redundant skin folds, 251
Intertrochanteric fractures, stabilization of, 1113
Intestinal anastomoses
of large intestine, 470–471
stapled, 471
sutured, 471
of small intestine, 440–447
definition for, 433
stapled, 444–447, 444*b*
inverting end-to-end, 444, 446*f*
side-to-side or functional, 444–447, 446*f*
triangulating end-to-end, 444, 445*f*
sutured, 440–444, 442*f*
with intestinal segments of disparate size, 440–441, 442*f*
modified simple continuous pattern for, 441–443, 443*f*
Intestinal biopsy
of large intestine, 469
of small intestine, 437–438
flexible endoscopic, 437
laparoscopic, 437–438
ultrasonographic, 437
Intestinal foreign bodies, 451–455
complications of, 455
definition for, 451
diagnosis of, 453–454
clinical presentation in, 453
imaging in, 453–454, 453*f*
laboratory findings in, 454
physical examination findings in, 453
differential diagnosis of, 454
endoscopic technique for, 454–455
general considerations and clinically relevant pathophysiology of, 451–452, 451*b*, 451*f*–453*f*
linear, 416, 452, 452*b*
medical management of, 454
postoperative care and assessment for, 455
prognosis for, 455
surgical technique for, 455
surgical treatment of, 454
anesthesia for, 454
positioning for, 454
preoperative management of, 454
surgical anatomy for, 454
suture materials and special instruments for, 455
Intestinal neoplasia
colorectal, 475–477
complications of, 477
definitions for, 475
diagnosis of, 475–476
clinical presentation in, 475
imaging in, 476
laboratory findings in, 476
physical examination findings in, 475–476
differential diagnosis of, 476
endoscopic biopsy of, 476
general considerations and clinically relevant pathophysiology, 475
medical management of, 476
Intestinal neoplasia *(Continued)*
postoperative care and assessment for, 477
prognosis for, 477
surgical technique for, 476–477
surgical treatment in, 476
anesthesia for, 476
positioning for, 476
preoperative management of, 476
surgical anatomy for, 476
suture materials and special instruments for, 477
of small intestine, 455–458
complications of, 458
definition for, 455
diagnosis of, 456–457
clinical presentation in, 456
imaging in, 457, 457*b*
laboratory findings in, 457
physical examination findings in, 456
differential diagnosis of, 457
general considerations and clinically relevant pathophysiology, 455, 456*b*, 456*f*
medical management of, 457
postoperative care and assessment for, 457–458
prognosis for, 458
surgical technique for, 457
surgical treatment of, 457
anesthesia for, 457
positioning for, 457
preoperative management of, 457
surgical anatomy for, 457
suture materials and special instruments for, 457
Intestinal plication
definition for, 433
due to foreign body, 416–417, 417*f*
to prevent recurrence of intussusception, 448, 448*b*, 448*f*
Intestinal resection and anastomoses
of large intestine, 470–471, 470*b*
with stapled anastomoses, 471
with sutured anastomoses, 471
of small intestine, 440–447
definition for, 433
with stapled anastomoses, 444–447, 444*b*
inverting end-to-end, 444, 446*f*
side-to-side or functional, 444–447, 446*f*
triangulating end-to-end, 444, 445*f*
with sutured anastomoses, 440–444, 442*f*
with intestinal segments of disparate size, 440–441, 442*f*
modified simple continuous pattern for, 441–443, 443*f*
Intestinal torsion, 464–466
definition for, 464
diagnosis of, 465
clinical presentation in, 465
imaging in, 465, 465*f*
laboratory findings in, 465
physical examination findings in, 465
differential diagnosis of, 465
Intestinal torsion *(Continued)*
general considerations and clinically relevant pathophysiology, 464–465, 464*f*
medical management of, 465
postoperative care and assessment for, 466
prognosis for, 466

prognosis for, 466
surgical technique for, 466
surgical treatment of, 465–466
anesthesia for, 466
positioning for, 466
preoperative management of, 465–466
surgical anatomy for, 466
suture materials and special instruments for, 466
Intestinal wall, layers of, 436, 436*b*
Intraarachnoid cyst. *see* Intracranial arachnoid cyst.
Intracapsular reconstruction, for cranial cruciate ligament, 1232*t*
Intracorporeally sutured laparoscopic gastropexy, 411–414
Intracranial arachnoid cyst, 1350–1353
definition for, 1350
diagnosis of, 1351–1352, 1352*f*
differential diagnosis of, 1352–1353
general considerations and clinically relevant pathophysiology of, 1350–1351
medical management of, 1353
postoperative care and assessment for, 1353, 1353*f*
prognosis of, 1353
surgical technique for, 1353
surgical treatment of, 1353
suture materials and special instruments for, 1353
Intracranial astrocytoma, 1360*f*
Intracranial pressure, defined, 1338, 1339*f*
Intradural/extramedullary pattern, in myelography, 1315, 1315*f*

Intrahepatic portosystemic shunts (IHPSS)
congenital, 550
defined, 550
history of, 552, 552*b*
hydraulic occlusion of, 561
intravascular occlusion of, 562
isolation and ligation of, involving left medial or lateral liver lobes, 561
ligation or attenuation of, 560–561, 561*b*
physical examination findings in, 552
prognosis for, 563
right-sided, isolation and ligation of, 561, 561*f*
signalment for, 551
ultrasound for, 552–553, 552*f*
Intraluminal stents, for tracheal collapse, 870–871
Intramedullary (IM) fixation, 1008–1016
interlocking nails for, 1011–1013
application of, 1012–1013, 1013*b*, 1013*f*
equipment and supplies for, 1012, 1012*f*
indications and biomechanical principles of, 1011–1012, 1012*f*
postoperative care for, 1013
intramedullary pins and Kirschner wires for, 1008–1011
application of, 1010–1011, 1010*b*, 1010*f*–1011*f*
equipment and supplies for, 1009–1010, 1010*f*
indications and biomechanical principles of, 1008–1009, 1009*f*
postoperative care for, 1011
orthopedic wire for, 1013–1015
application of, 1014, 1014*b*, 1015*f*
cerclage and hemicerclage wire in, 1013
equipment and supplies for, 1014
indications and biomechanical principles of, 1013–1014, 1013*f*–1014*f*
postoperative care for, 1015
tension bands for, 1015–1016
application of, 1015–1016, 1016*b*
equipment and supplies for, 1015
indications and biomechanical principles of, 1015, 1015*f*
postoperative care for, 1016
Intramedullary pattern, in myelography, 1315–1316, 1315*f*–1316*f*
Intramedullary (IM) pins
for cervical spondylomyelopathy, 1385, 1386*f*
defined, 958*b*
external skeletal fixators with, 1002
for femoral fractures, 1104–1105, 1105*b*, 1105*f*
for humeral diaphyseal fractures, 1055–1056, 1056*b*, 1056*f*
for intramedullary fixation, 1008–1011
application of, 1010–1011
as crossed pins, 1011, 1011*f*
key concepts for, 1010*b*
with normograde placement, 1010–1011, 1010*f*
with retrograde placement, 1010–1011, 1011*f*
Intramedullary (IM) pins *(Continued)*
equipment and supplies for, 1009–1010, 1010*f*
indications and biomechanical principles of, 1008–1009, 1009*f*
postoperative care for, 1011
partial carpal arthrodesis with, 1205–1206
for radial diaphyseal fractures, 1069, 1069*b*
for tibial diaphyseal fractures, 1123, 1124*f*
Intramembranous bone formation, 958*b*, 1025
Intramembranous bone healing, 1027–1028, 1028*f*–1029*f*
Intraocular prosthetic (ISP), definition for, 291
Intraparenchymal hemorrhage, 1362–1363, 1363*f*
Intrapelvic urethral anastomosis, 686–687, 687*f*, 689*f*
Intrarenal abscesses. *see* Renal abscesses.
Intrasite Gel (hydrogel dressing), 197*t*–198*t*, 198–199
Intravascular coils, for patent ductus arteriosus, 802, 803*f*
Intravascular occlusion, of intrahepatic portosystemic shunts, 562
Intravenous fluids, for gastric dilatation-volvulus, 423
Intravenous (IV) regional anesthesia, 152
Intussusception, 458–462
gastroesophageal, 390–391
of small intestine
bowel plication to prevent recurrence of, 448, 448*b*, 448*f*
definition for, 458, 458*f*
diagnosis of, 459–460
clinical presentation in, 459, 459*b*
imaging in, 459–460, 460*f*
laboratory findings in, 460
physical examination findings in, 459
differential diagnosis of, 460–461
general considerations and clinically relevant pathophysiology, 458–459, 459*b*
medical management of, 461
postoperative care and assessment for, 461–462
prognosis for, 462
surgical technique for, 461, 461*b*, 461*f*
surgical treatment of, 461
anesthesia for, 461
positioning for, 461
preoperative management of, 461
surgical anatomy for, 461
suture materials and special instruments for, 461
Intussusceptum, 458
Intussuscipiens, 458
Inverting end-to-end stapled intestinal anastomoses, 444, 446*f*
Inverting sutures, 68
Iodinated contrast, 170
Iodine, for sterile skin preparation, 38, 38*t*, 39*f*
Iodine compounds, as disinfectant, 5*t*
Iodophors
as disinfectants, 5*t*
for sterile skin preparation, 38, 38*t*, 39*f*
for surgical scrub, 46*t*
IOHC. *see* Incomplete ossification of humeral condyle.
Ionizing radiation, for sterilization, 9–10
IPA (isopropyl alcohol), as disinfectant, 5*t*
Irreducible minimum, 2*b*
Irregular skin defects, 214–217
circular, 214–215, 214*f*
crescentic, 217, 217*f*
fusiform, 217, 217*f*
square and rectangular, 215, 216*f*
triangular, 215, 215*f*
Ischemic necrosis, of bowel, 436–437
Ischemic/vascular disease, 1448–1453
definitions for, 1448
diagnosis of, 1448–1451, 1450*t*, 1451*f*
differential diagnosis of, 1451, 1452*b*
general considerations and clinically relevant pathophysiology, 1448, 1448*f*
medical management of, 1451
prognosis for, 1452–1453
surgical treatment of, 1451
Ischial fractures, 1095
definitions for, 1095
diagnosis of, 1095, 1096*f*
differential diagnosis of, 1096
general considerations and pathophysiology of, 1095–1099, 1095*b*
medical management of, 1096
prognosis for, 1099
surgical treatment of, 1096–1097, 1096*b*
anesthesia for, 1096
application of plates and screws in, 1096
complications in, 1099
positioning for, 1097
postoperative care and assessment after, 1098–1099
preoperative management of, 1096
surgical anatomy for, 1096–1097, 1096*b*
surgical technique for, 1097–1098, 1098*f*
suture materials and special instruments for, 1098
Ischiocavernosus muscle, 686*f*, 727
Ischiopubic symphysis, 686*f*
Ischium, 1096
Island flaps, 217
Islet cell adenocarcinoma. *see* Insulinomas.
Isobutyl-2 cyanoacrylate adhesives (Vetbond, LiquiVet, GLUture), 66–67, 191
Isoflurane, 127*t*–131*t*, 135
Isometric contractions, 106
Isometry, 1227
Isopropyl alcohol (IPA), as disinfectant, 5*t*
Isoproterenol (Isuprel), for bradycardia, 828*b*
Isotonic contractions, 106
Isotonic crystalloid solutions, 32*t*

J
Jackets, for surgical team, 42
Jackson-Henderson approach, to patent ductus arteriosus, 804–805
Jackson-Pratt drain, 535*f*
  for pleural effusion, 922–923, 922*f*
Jamshidi bone marrow biopsy needle, 1302, 1303*f*
Jejunal portography, 559, 559*f*
Jejunum, 436
Jelonet (paraffin-impregnated) dressing, 196, 197*t*–198*t*
Jewelry, in surgical scrub, 44
Joint(s)
  cartilaginous, 1134, 1141*b*
  fibrous, 1134, 1141*b*
  synovial, 1134, 1141, 1141*b*, 1141*f*
Joint cavity, 1141*f*
Joint disease, 1134–1279
  of carpal joint, 1202–1209
    carpal laxity syndrome as, 1208–1209
    carpal luxation or subluxation as, 1202–1206
      resulting from collateral ligament injury, 1206–1208
  classified, 1134, 1135*b*
  continuous passive motion for, 1143
  of coxofemoral joint, 1209–1227
    coxofemoral luxation as, 1220–1225
    hip dysplasia as, 1209–1220
    Legg-Perthes disease, 1225–1227, 1226*f*
  definitions for, 1134
  degenerative, 1143–1146
    asymptomatic, 1145*b*
    definition for, 1143
    diagnosis of, 1144
      arthroscopy in, 1144, 1145*f*
      clinical presentation in, 1144
      imaging in, 1135*t*, 1144, 1144*f*
    differential diagnosis of, 1145
    general considerations and clinically relevant pathophysiology, 1144
    laboratory findings in, 1144
    medical management of, 1145
      antiinflammatory drugs as, 1140*t*
      chondroprotective agents for, 1137
      glucocorticoids for, 1145, 1145*b*
      NSAIDs for, 1145, 1145*b*
      principles of, 1137*b*
    physical examination in, 1144
    primary, 1144
    prognosis for, 1146, 1146*b*
    secondary, 1144
    surgical treatment of, 1145–1146
  diagnosis of, 1134–1137
    clinical presentation in, 1134
    imaging in, 1134–1135, 1135*t*
    laboratory findings in, 1135–1137, 1135*t*
    physical examination in, 1134
    synovial fluid collection in, 1135–1137, 1136*f*, 1137*b*
  differential diagnosis of, 1137
  of elbow joint, 1174–1202
    canine elbow dysplasia, 1174
    elbow luxation
      congenital, 1200–1202
      traumatic, 1193–1197
Joint disease *(Continued)*
    elbow subluxation, caused by premature closure of the distal ulnar or radial physes, 1197–1200
  feline chronic progressive polyarthritis as, 1153–1154
  general considerations with, 1134
  healing of cartilage defects in, 1142–1143, 1143*f*
  joint immobilization for, 1143
  joint stabilization for, 1143
  lyme arthropathy as, 1149–1151, 1150*b*
  medical management of, 1137–1141
    exercise moderation in, 1137, 1139*b*
    medical therapies in, 1139–1141
      antibiotics as, 1139–1140, 1140*t*
      glucocorticoids as, 1140–1141
      nonsteroidal antiinflammatory drugs in, 1139, 1139*b*, 1139*f*, 1140*t*
      polysulfated glycosaminoglycans and hyaluronic acid (HA) as, 1139
    nutritional supplementation in, 1137
      with omega-3 fatty acids, 1137
      with slow-acting, disease-modifying osteoarthritis agents, 1137
    physical rehabilitation therapy in, 1137, 1139*b*
    weight management in, 1137, 1137*b*, 1138*f*
  nonerosive idiopathic immune-mediated polyarthritis, 1151–1152, 1151*b*
  postoperative care for, 1143
    nutritional management in, 1143
    physical rehabilitation in, 1143
  rheumatoid arthritis as, 1152–1153
  rickettsial and anaplasmal polyarthritis, 1149
  scapular luxation as, 1172–1173
  septic (bacterial) arthritis, 1146–1149
  of shoulder, 1154–1173
    biceps tendon disease as, 1169–1172
    osteochondritis dissecans
      arthroscopic treatment of, 1156–1158
        indications for, 1156
        instrumentation for, 1156, 1156*b*
        portal sites and technique for, 1156–1158, 1157*f*–1158*f*
        postoperative care and assessment for, 1158
      definitions for, 1154
      diagnosis of, 1155–1156, 1155*b*, 1156*f*
      differential diagnosis of, 1156
      general considerations and clinically relevant pathophysiology, 1154–1155, 1155*b*, 1155*f*
      medical management of, 1156
      open surgical techniques for, 1158*b*
        caudal approach for, 1159
        infraspinatus tenotomy for, 1158–1159
        postoperative care and assessment after, 1159
        surgical treatment of, 1156–1158
Joint disease *(Continued)*
        prognosis of, 1159
        surgical treatment of, 1156–1158
    scapulohumeral joint luxation as, 1159–1167
    shoulder instability as, 1167–1169
  stifle, 1227–1266
    caudal cruciate ligament injury as, 1248–1250
    collateral ligament injury as, 1250–1252
    cranial cruciate ligament rupture, 1227–1243
    meniscal injury as, 1243–1248
    multiple ligament injuries as, 1252–1254
    osteochondritis dissecans as, 1264–1266
      definition for, 1264
      diagnosis of, 1264–1265, 1265*f*
      differential diagnosis of, 1265
      general considerations and clinically relevant pathophysiology, 1264
      medical management of, 1265
      prognosis of, 1266
      surgical treatment for, 1265–1266
    patellar luxation as
      lateral, 1261–1264
      medial, 1254–1261
  surgical anatomy of, 1141–1142, 1141*b*, 1141*f*–1142*f*
  surgical technique for, 1142
    arthrotomy as, 1142, 1142*b*
    closed *vs.* open joint reduction, 1142, 1142*t*
    endoscopically assisted joint surgery, 1142
  of tarsus, 1266–1277
    ligament injury as, 1266–1272
      definition for, 1266
      diagnosis of, 1266–1267, 1267*f*–1268*f*
      differential diagnosis of, 1267
      general considerations and clinically relevant pathophysiology, 1266–1267
      medical management of, 1267
      prognosis of, 1272
      surgical treatment for, 1267–1269
        anesthesia for, 1268
        complications of, 1271
        partial tarsal arthrodesis in, 1270, 1270*f*
        positioning for, 1268–1269
        postoperative care after, 1271
        preoperative management of, 1268
        shearing injuries in, 1269–1270, 1270*b*, 1270*f*
        surgical anatomy for, 1268, 1269*f*
        suture materials and special instruments for, 1271
        tarsocrural joint arthrodesis (pan tarsal arthrodesis), 1270–1271, 1271*f*
        tarsocrural luxation or subluxation in, 1268*f*–1269*f*, 1269

Joint disease *(Continued)*
tarsometatarsal luxation in, 1270, 1271*f*
osteochondritis dissecans as, 1272–1277
definition for, 1272
diagnosis of, 1272
arthroscopy in, 1272, 1273*f*
clinical presentation in, 1272, 1272*b*
imaging in, 1272, 1272*b*, 1272*f*–1273*f*
physical examination in, 1272
differential diagnosis of, 1272–1274
general considerations and clinically relevant pathophysiology, 1272
medical management of, 1274
prognosis for, 1276–1277, 1277*b*
surgical treatment of, 1274
anesthesia for, 1274
arthroscopy in, 1274
arthrotomy in, 1274
dorsolateral approach to, 1275
dorsomedial approach for, 1274
plantarolateral approach to, 1275–1276, 1276*f*
plantaromedial approach to, 1274, 1275*f*
positioning for, 1274
postoperative care after, 1276
preoperative management of, 1274
surgical anatomy for, 1274
suture materials and special instruments for, 1276
Joint immobilization, 1143
Joint mice, 1154
Joint neoplasia, 1308–1309, 1309*f*
Joint reduction, closed *vs.* open, 1142, 1142*t*
Joint stability, loss of, 1141
Joint stabilization, 1143
Joint surgery, rehabilitation after, 123, 123*b*
JPS (juvenile pubic symphysiodesis), 1212, 1215, 1215*f*
Julian thoracic artery forceps, 796*f*
Jump-down syndrome. *see* Fragmented coronoid process.
Juvenile hip dysplasia, palpation for, 965–966
Juvenile osteomyelitis, 1295–1296, 1295*b*–1296*b*, 1296*f*
Juvenile pubic symphysiodesis (JPS), 1212, 1215, 1215*f*

K

Kanamycin, 82
Keflex (cephalexin), 80*t*
for renal surgery, 653*b*
Kefzol. *see* Cefazolin.
Kelly hemostat forceps, 53–54, 53*f*
Keratoconjunctivitis sicca (KCS), 281
Kerlix antimicrobial dressing (Kerlix AMD), 197*t*–198*t*, 199–200
for outer layer of bandage, 201
Ketamine, 144, 148*t*–149*t*
brain surgery and, 1342
for ear surgery, 302–303
for induction, 127*t*–131*t*, 134–135
for liver surgery, 540–542, 541*t*–542*t*
Ketamine *(Continued)*
with peritonitis, 533–534
for placement of a temporary pacemaker, 829*b*
Ketoconazole (Nizoral)
for hyperadrenocorticism, 593
for perianal fistula, 502–503, 503*b*
Ketoprofen, 148*t*–149*t*, 150
Keyhole biopsy, of lung, 893
Ki67 index, 611–612
Kidney(s), 650–677
abscesses of, 675–677
biopsy of, 654–655, 654*b*–655*b*
laparoscopically-guided, 655
surgical, 655, 655*f*
needle, 655
wedge, 655
ultrasound-guided percutaneous, 654, 655*f*
calculi of, 669–673
definitions for, 650
healing of, 662, 662*b*
neoplasia of, 673–675
complications of, 675
definition for, 673
diagnosis of, 674
differential diagnosis of, 674
general considerations and pathophysiology of, 673–674, 673*b*–674*b*
medical management of, 674
postoperative care and assessment for, 675
prognosis of, 675
special age considerations for, 675
surgical technique of, 675
surgical treatment for, 674–675, 675*f*
suture materials and special instruments for, 675
surgical anatomy of, 653–654, 654*b*
surgical technique for, 654–662
for biopsy, 654–655, 654*b*–655*b*
laparoscopically-guided, 655
needle, 655
surgical, 655, 655*f*
ultrasound-guided percutaneous, 654, 655*f*
wedge, 655
for nephrectomy, 655–656, 656*b*, 656*f*
partial, 656, 657*f*
for nephrostomy tube placement, 660–662
for nephrotomy, 656–657, 658*f*
for pyelolithotomy, 657, 658*f*
surgical treatment of
anesthetic considerations for, 650–653, 652*t*–653*t*
antibiotics for, 653, 653*b*
complications of, 663
intraoperative considerations for, 652*t*–653*t*
postoperative care after, 652*t*–653*t*, 662–663
preoperative management of, 650, 650*b*–651*b*, 652*t*–653*t*
special age considerations for, 663
suture materials and special instruments for, 662
Kidney disease, chronic
defined, 650
staging system for, 650, 651*b*
Kidney injury, acute
defined, 650
preoperative management of, 650
Kinematic analysis, 107
Kirschner wires
for capital physeal fractures, 1116–1117, 1117*f*
for craniocervical junction anomalies, 1392, 1392*f*
for femoral neck fractures, 1113, 1113*f*
for intramedullary fixation, 1008–1011
application of, 1010–1011, 1010*b*
with cerclage wire, 1010
equipment and supplies for, 1009–1010, 1010*f*
indications and biomechanical principles of, 1008–1009, 1009*f*
postoperative care for, 1011
for mandibular fractures, 1038, 1039*f*
for proximal radial physeal fractures, 1078, 1079*f*
for scapular neck fractures, 1051, 1051*f*
for talar trochlear fractures, 1085*f*, 1086
for thoracolumbar spinal trauma, 1422–1423, 1423*f*
Klebsiella spp., pyothorax due to, 948*t*
Knee, arthroscopy of, 166*b*
Knot(s), 71–74, 71*f*
burying of, 74, 76*f*
granny, 71, 71*f*
half-hitch (tumbled), 71, 71*f*
hand ties for, 72, 73*f*–75*f*
instrument ties for, 72, 72*f*
square, 71, 71*f*
strangle, 71–72, 72*f*
tensile strength of, 61*b*
Knot security, relative, 60
Knot strength, 61*b*
Knot tensile strength, 60
Knotless barbed suture, 64, 64*f*
Knot-pull tensile strength, 61*b*
Knuckling, due to cauda equina lesions, 1427
Koilosternia. *see* Pectus excavatum.

L

Laboratory coats, for surgical team, 42
Laboratory data, 26, 26*b*, 28*t*
Lacerations, 183, 1282
eyelid, 272–273
of footpad, 263
Lacrimal caruncle, 268
β–lactam antibiotics, 79–80, 82*b*
Lactate levels, in peritonitis, 528–529
Lactated Ringer's solution (LRS), 31
as wound cleanser, 184, 184*t*
Lactulose (Chronulac)
after prostatic or perineal surgery, 744*b*
for portosystemic shunts, 555, 555*b*
Lacunar infarcts, 1448
Ladder walking, as therapeutic exercise, 121
Lag phase, in healing of small intestine, 449
Lag screws, 1017
application of, 1019–1020, 1020*b*, 1020*f*
for avulsed metacarpal or metatarsal fractures, 1088, 1088*f*

Lag screws *(Continued)*
for capital physeal fractures, 1117, 1117*f*
for femoral bicondylar fracture, 1113, 1113*f*
for femoral unicondylar fracture, 1113, 1113*f*
for iliac fractures, 1098, 1098*f*
for malleolar fractures, 1130, 1130*f*
partial carpal arthrodesis with, 1206
for talar trochlear fractures, 1085*f*, 1086
for ununited anconeal process, 1190–1191, 1191*f*
Lagophthalmos, definition for, 284
Lameness, differential diagnosis for, 959*t*
Lameness scoring system, 106–107, 107*b*
Lamina, 1405*f*
Laminectomy
cranial cervical
for cranial cervical laminectomy, 1372–1373, 1372*f*
dissection on midline of superficial cervical musculature in, 1372–1373, 1372*f*
for dorsal midcervical laminectomy, 1372–1373, 1373*f*
elevation of muscle from spinous process and laminae in, 1372–1373, 1373*f*
extent of defect in, 1373, 1374*f*
positioning for, 1370–1372, 1371*f*
separation of median raphe in, 1372–1373, 1372*f*
dorsal, 1365
for cauda equina lesions, 1429–1430, 1429*f*
for cervical spondylomyelopathy, 1386, 1389*f*
defined, 1404, 1427
of lumbosacral junction, 1433
midcervical, 1372–1373, 1373*f*
of thoracolumbar spine, 1407*f*–1408*f*
Lanoxin (digoxin), for gastric dilatation-volvulus, 425*b*
Laparoscopic biopsy, of small intestine, 437–438
Laparoscopic cholecystectomy, 574, 575*f*
Laparoscopic gastropexy
prophylactic, 410, 413*f*
single-port, 414
sutured, 410
intracorporeally, 411–414
Laparoscopic liver biopsy, 545–546, 546*b*
Laparoscopic pancreatic biopsy, 604
Laparoscopic partial splenectomy/splenic biopsy, 641
Laparoscopically assisted cystoscopy, for bladder and urethral calculi, 704
Laparoscopically-guided renal biopsy, 655
Laparoscopic-assisted cholecystostomy, 574
Laparoscopic-assisted ovariectomy, 730–732, 732*f*
Laparoscopic-assisted ovariohysterectomy, 730–732, 732*f*
Laparoscopy
defined, 158
equipment for, 163, 163*f*
indications for, 159*b*
Laparotomy
defined, 512
exploratory
for peritonitis, 532, 534
preoperative management of, 512–513
technique for, 534
gastrostomy tube placement by midline, 98
Large bowel. *see* Large intestine.
Large intestine, 466–482
anesthetic considerations for, 467
antibiotics for, 467–468, 468*b*
bacteria in, 473, 473*b*
colitis of, 477–479
complications of, 474
definitions for, 466
healing of, 473, 473*b*
megacolon of, 479–482
neoplasia of, 475–477
complications of, 477
definitions for, 475
diagnosis of, 475–476
differential diagnosis of, 476
endoscopic biopsy of, 476
general considerations and clinically relevant pathophysiology, 475
medical management of, 476
postoperative care and assessment for, 477
prognosis for, 477
surgical technique for, 476–477
surgical treatment in, 476
suture materials and special instruments for, 477
postoperative care and assessment for, 474, 474*b*
preoperative concerns for, 466–467, 467*b*
special age considerations for, 475
surgical anatomy of, 468, 468*b*
surgical techniques for, 468–473, 469*b*
for biopsy, 469
for colon resection and anastomosis, 470–471, 470*b*, 470*f*
for colopexy, 469–470, 469*f*
for colostomy, 471–473
for end-on colostomy, 473
for typhlectomy, 471, 472*f*–473*f*
suture materials and special instruments for, 473
Laryngeal collapse, 856–858
clinical presentation of, 857
definitions for, 856
diagnosis of, 857
diagnostic imaging for, 857
differential diagnosis of, 857
general considerations and clinically relevant pathophysiology, 856–857
laboratory findings in, 857
medical management of, 857–858
physical examination findings in, 857
postoperative care and assessment for, 858
prognosis of, 858
surgical treatment of, 858
Laryngeal examination, anesthetic considerations for, 834–836, 835*t*
Laryngeal function, evaluation of, 1325–1328
Laryngeal inlet, 839*f*
Laryngeal paralysis, 858–863
clinical presentation of, 859
definition for, 858
diagnosis of, 859–860
diagnostic imaging for, 859–860
differential diagnosis of, 860
general considerations and clinically relevant pathophysiology, 858–859, 859*b*
laboratory findings in, 860, 860*b*
medical management of, 860–861, 860*b*
physical examination findings in, 859
prognosis of, 863
surgical treatment of, 861
anesthesia for, 861
complications with, 862–863
partial laryngectomy for, 861–862
positioning for, 861
postoperative care and assessment for, 862
preoperative management of, 861
surgical anatomy for, 861
unilateral arytenoid lateralization for, 861, 862*f*
Laryngeal saccules, 838–839
Laryngeal tumors, 864–868, 864*b*
clinical presentation of, 865
complications with, 868
definition for, 864
diagnosis of, 865–866
diagnostic imaging for, 866, 866*f*
differential diagnosis of, 866–867
general considerations and clinically relevant pathophysiology, 864–865
laboratory findings in, 866
medical management of, 867
physical examination findings in, 865–866
postoperative care and assessment for, 868
prognosis of, 868
surgical treatment of, 867
suture materials and special instruments for, 868
Laryngeal ventricles, 838–839
Laryngeal wounds, healing of, 846
Laryngectomy
complete or total, for laryngeal and tracheal tumors, 867–868
partial
for laryngeal and tracheal tumors, 867
for laryngeal paralysis, 861–862
Laryngoscopy, 158, 159*b*, 162
for brachycephalic syndrome, 853
for epiglottic retroversion, 863
for laryngeal and tracheal tumors, 866, 866*f*
for laryngeal collapse, 857, 857*f*
for laryngeal paralysis, 860
for tracheal collapse, 869
Larynx, 838, 839*f*
Laser Doppler velocimetry, to assess skin viability, 189–190
Laser therapy, 113–114, 113*b*–114*b*, 113*f*
Lasix. *see* Furosemide.
Lateral atlanto-occipital ligament, 1368*f*
Lateral bulla osteotomy, 309–310, 312*f*
Lateral canthus, 268

Lateral caudal axial pattern flap, 226
Lateral cervical nucleus (LCN), 140–141
Lateral collateral ligament, 1251, 1252*f*
Lateral collateral ligament injury, 1252
  definition for, 1250–1252
  diagnosis of, 1250–1251
    clinical presentation in, 1250
    imaging in, 1251, 1251*f*
    laboratory findings in, 1251
    physical examination in, 1250, 1250*f*, 1251*b*
  differential diagnosis of, 1251
  general considerations and clinically relevant pathophysiology, 1250
  medical management for, 1251
  prognosis for, 1252
  surgical treatment for, 1251, 1251*b*
    anesthesia for, 1251, 1252*f*
    positioning for, 1251
    postoperative care after, 1252
    preoperative management of, 1251
    surgical anatomy for, 1251
    suture materials and special instruments for, 1252
Lateral corpectomy
  partial, 1404
  for thoracolumbar disc disease, 1413–1414, 1414*f*
Lateral craniotomy, 1338, 1343, 1345*f*
Lateral digital extensor muscle, 1078*f*
Lateral distal radial angle, 1081
Lateral ear canal resection, 306–307, 306*b*, 306*f*–307*f*
Lateral enucleation, for glaucoma, 299–300, 299*f*
Lateral extracapsular stabilization, for cranial cruciate ligament rupture, 1235–1237, 1236*f*
Lateral imbrication, for medial patellar luxation, 1260–1261, 1261*f*
Lateral meniscus, 1234*f*
Lateral palpebral ligament, 268
Lateral patellar luxation, 1261–1264
  definition for, 1261
  diagnosis of, 1261–1263
  differential diagnosis of, 1263
  general considerations and clinically relevant pathophysiology, 1261
  medical management for, 1263
  prognosis for, 1264
  surgical treatment for, 1263, 1264*f*
Lateral retinaculum, 1257
Lateral thoracic axial pattern flap, 224
Latissimus dorsi myocutaneous flap, 227, 227*f*
Lavage, diagnostic peritoneal, 531, 534, 534*b*, 534*f*
Laxatives, after large intestinal surgery, 474, 474*b*
LCN (lateral cervical nucleus), 140–141
LDDS (low-dose dexamethasone) suppression test, 592
Leeches, 204
Leflunomide
  for immune-mediated polyarthritis, 1151–1152, 1151*b*
  for noninfectious inflammatory disease, 1455*b*
  for rheumatoid arthritis, 1153*b*
Left coronary artery, 800–801, 800*f*
Left gastroepiploic artery and vein, 604*f*, 639, 639*f*
Left lateral liver lobe
  complete lobectomy of, 547–548
  isolation and ligation of intrahepatic portosystemic shunt involving, 561
Left medial liver lobe, 543*f*
  complete lobectomy of, 548
  isolation and ligation of intrahepatic portosystemic shunt involving, 561
Left recurrent laryngeal nerve, 795
Left subclavian artery, 794–795
Left ventricle, 794*f*
Left-handed surgeons
  instrument grip for, 52*b*
  scissors use by, 50
Leg bandage, 204, 205*f*
Legg-Perthes disease, 1225–1227
  definition for, 1225
  diagnosis of, 1226, 1226*f*
  differential diagnosis of, 1226
  general considerations and clinically relevant pathophysiology, 1225–1226, 1226*b*
  medical management of, 1226
  prognosis for, 1227
  surgical treatment for, 1226–1227
Leiomyoma(s)
  of bladder, 711*f*
  definition for, 430
  gastric, 431
  of large intestine, 475
  uterine, 751, 751*f*
  vaginal, 740*f*
Leiomyosarcoma(s)
  definition for, 430
  intestinal, 456, 475
  prostatic, 771
  splenic, 645*f*
  uterine, 751
Lembert suture pattern, 70, 70*f*
Lengthening osteotomy, 1035
Leukeran (chlorambucil), for feline chronic progressive polyarthritis, 1154*b*
Leukocytosis, in peritonitis, 528–529
Leukoencephalitis, necrotizing, 1453
Leukoma, 281
Levator anguli oculi medialis muscle, 268
Levator palpebrae superioris muscle, 268
Levetiracetam, for brain surgery, 1339–1340, 1339*t*
Levophed (norepinephrine), for cardiac disease, 789*b*
Levothyroxine (Soloxine), for hypothyroidism, 615*b*
Leydig cell(s), 772
Leydig cell tumors, 773
LH (luteinizing hormone), in females, 720–721
Lick granulomas, 248–249, 248*f*
  treatment of, 249
Lidocaine (Xylocaine), 144–150, 148*t*–149*t*
  for anesthesia, 127*t*–131*t*, 133
  for gastric dilatation-volvulus, 423–424, 425*b*
  for inflow occlusion, 793*b*
Lidocaine (Xylocaine) *(Continued)*
  for pheochromocytoma, 594–596, 595*t*–596*t*, 596*b*
  toxicity of, 423–424, 423*b*
Life vests, 122
Ligaclips, 67
Ligament(s)
  repair of, stem cells for, 973
  supporting, 1141*f*
Ligament injuries
  multiple, 1252–1254
    definitions for, 1252
    diagnosis of, 1253
    differential diagnosis of, 1253
    general considerations and clinically relevant pathophysiology, 1252–1253
    medical management of, 1253
    prognosis for, 1254
    surgical treatment for, 1253–1254, 1254*f*
  of tarsus, 1266–1272
    definition for, 1266
    diagnosis of, 1266–1267, 1267*f*–1268*f*
    differential diagnosis of, 1267
    general considerations and clinically relevant pathophysiology, 1266–1267
    medical management of, 1267
    prognosis of, 1272
    surgical treatment for, 1267–1269
      anesthesia for, 1268
      complications of, 1271
      partial tarsal arthrodesis in, 1270, 1270*f*
      positioning for, 1268–1269
      postoperative care after, 1271
      preoperative management of, 1268
      shearing injuries in, 1269–1270, 1270*b*, 1270*f*
      surgical anatomy for, 1268, 1269*f*
      suture materials and special instruments for, 1271
      tarsocrural joint arthrodesis (pan tarsal arthrodesis), 1270–1271, 1271*f*
      tarsocrural luxation or subluxation in, 1268*f*–1269*f*, 1269
      tarsometatarsal luxation in, 1270, 1271*f*
Ligament rupture, 1141
Ligamentum arteriosum, thoracoscopic ligation and division of, 397, 397*f*
Ligamentum flavum malformation, 1381*t*
Ligamentum venosum, 543*f*
LigaSure (electrothermal feedback-controlled bipolar vessel sealing system), 78
Ligating clips, 67
Ligation, for hemostasis, 75
Light cable, for arthroscopy, 168
Lighting, for operating room, 21, 21*f*
Limb, draping of, 40, 40*f*
Limb deformities, CT of, 172
Limb-sparing techniques, for bone neoplasia, 1305
  bone biopsy and, 1302*b*
  cortical allograft with carpal arthrodesis, 1305, 1308*f*

Limbus, 281
Limited-contact dynamic compression plate, 1018, 1018*f*
Linea alba, 513*b*, 520*f*
  closure of, 517, 518*b*
Linear attenuation coefficients, 170
Linear cutting stapler, 444–447
Linear external fixator, 998–1003
  with acrylic splints, 1002
  application of, 1000–1002, 1001*b*
  bilateral-biplanar (type III), 998*f*, 1002
  bilateral-uniplanar (type II), 998*f*, 1001–1002
  equipment and supplies for, 999–1000
    external connectors as, 999–1000, 1000*f*
    fixation pins as, 999, 999*f*
    linkage devices as, 1000, 1000*f*
  indications and biomechanical principles of, 998–999, 998*b*, 998*f*
  with intramedullary pins, 1002
  postoperative care for, 1002–1003
  tie-in, 998*f*
  unilateral-biplanar (type Ib), 998*f*, 1001
  unilateral-uniplanar (type Ia), 998*f*, 1001, 1001*b*
Linear foreign bodies, 416, 452, 452*b*
Linear technique, for circular skin defects, 214, 214*f*
Linear traction views, of caudal cervical spondylomyelopathy, 1382–1383
Linen, unwrapping after, 14–16, 16*f*
Linezolid (Zyvox), as drug of last resort, 82–83
Linkage devices, for linear external fixator, 1000, 1000*f*
Lion's jaw, 1298–1299, 1299*b*, 1299*f*
Lip fold(s), 251
  antidrool cheiloplasty in, 251, 253*f*
  lip fold resection (cheiloplasty) in, 251, 252*f*
Lip fold resection, 251, 252*f*
Liposarcoma, 1300*t*
Liquid diets, 90–91, 93*t*
LiquiVet (cyanoacrylate tissue adhesives), 66–67, 191
Lisinopril (Prinivil, Zestril), for cardiac disease, 789*b*
Lister, Joseph, 43
Lithonephrotomy, 669
Lithotripsy, 670
  for bladder and urethral calculi, 704
Liver
  healing of, 549
  surgical anatomy of, 543, 543*f*, 544*b*
Liver biopsy
  indications for, 544*b*
  laparoscopic, 545–546, 546*b*
  percutaneous, 544–545
    blind, 545
    false-negative results in, 545*b*
    fine-needle aspiration and, 545
    sedation for, 545
    ultrasound-guided, 545
  preoperative concerns for, 540*b*
  surgical, 546, 547*f*
  tissue core, 544, 544*f*
Liver disease
  focal *vs.* diffuse, 544
  gastric ulceration and erosion due to, 428
Liver lobe torsions. *see* Hepatic lobe torsion.
Liver surgery, 540–570
  anesthetic considerations for, 540–543, 541*t*–542*t*
  antibiotics for, 543, 543*b*
  biopsy as
    indications for, 544*b*
    laparoscopic, 545–546, 546*b*
    percutaneous, 544–545
    preoperative concerns for, 540*b*
    preoperative concerns in, 540*b*
    surgical, 546, 547*f*
  for cavitary hepatic lesions, 563–566
  complications of, 549
  definitions for, 540
  healing of liver after, 549
  for hepatic lobe torsion, 568–569
  for hepatobiliary neoplasia, 566–568
  lobectomy as
    complete, 547–549
    partial, 546–547, 548*f*
  for portosystemic vascular anomalies, 550–563
  postoperative care and assessment in, 549
  preoperative concerns in, 540
  special age considerations for, 549–550
  surgical anatomy for, 543, 543*f*, 544*b*
  surgical techniques for, 544–549
  suture materials and special instruments for, 549
LLT. *see* Lung lobe torsion.
LMN (lower motor neuron), innervation of, 1365
LMN (lower motor neuron) paresis/plegia, 1330
LMN (lower motor neuron) weakness, 1365
Load, defined, 106
Lobectomy, of liver
  complete, 547–549
    of caudate process of the caudate liver lobe, 549
    of central division of the liver, 548–549
    of left lateral liver lobe, 547–548
    of left medial liver lobe, 548
    of right lateral liver lobe, 549
  partial, 546–547, 548*f*
Local flaps, 217
Locking compression plate, 1017–1018, 1017*f*
Locking screws, 1016–1017
  application of, 1021
Lomotil (diphenoxylate with atropine), for tracheal collapse, 871*b*
Lomustine, for brain tumors, 1359–1360, 1360*b*
Long lateral collateral ligament, 1268, 1269*f*
Long medial collateral ligament, 1268, 1269*f*
Long oblique fractures, 983–984
Longitudinal relaxation, 169
Longus colli muscles, 1369*f*
Lotensin (benazepril)
  for cardiac disease, 789*b*
  for congestive heart failure, 809*b*
Low molecular weight heparin (Dalteparin), for peritonitis, 531, 531*b*
Low-dose dexamethasone (LDDS) suppression test, 592
Lower motor neuron (LMN), innervation of, 1365
Lower motor neuron (LMN) paresis/plegia, 1330
Lower motor neuron (LMN) weakness, 1365
Lower respiratory system surgery
  lungs and thoracic wall, 884–915
    anesthesia for, 884–888, 885*t*–886*t*, 886*b*–887*b*
    antibiotics for, 888
    complete lobectomy for, 894–895, 896*f*
    complications of, 897, 897*b*
    definitions for, 884
    healing after, 895–896
    lung biopsy for, 893–894
    for lung lobe torsion, 905–907
    partial lobectomy for, 894, 895*f*
    for pectus excavatum, 907–912
    postoperative care and assessment for, 897, 897*b*
    preoperative management of, 884, 884*b*
    for pulmonary abscesses, 903–905
    for pulmonary neoplasia, 900–903
    special age considerations for, 897
    surgical anatomy for, 888–889, 889*f*–890*f*
    surgical materials and special instruments for, 896–897, 896*f*
    for thoracic wall neoplasia, 912–914
    for thoracic wall trauma, 897–900
    thoracotomy for, 889–893, 889*b*, 889*t*
  of pleural cavity and diaphragm, 916–955
    anesthetic considerations for, 918, 918*b*, 919*t*–920*t*
    antibiotics for, 918
    for chylothorax, 941–947
    complications of, 926
    definitions for, 916
    healing after, 924–925, 926*f*
    for mediastinal cysts, 951–954
    for peritoneopericardial diaphragmatic hernia, 931–933
    for pleural effusion, 937–941
    for pneumothorax, 933–937
    postoperative care and assessment for, 925
    preoperative concerns in, 916–918, 916*b*–917*b*, 917*t*
    for pyothorax, 947–951
    special age considerations to, 926
    surgical anatomy for, 918–920
    surgical techniques of, 920–924
      continuous thoracic suction for, 924, 925*f*–926*f*
      needle thoracentesis for, 920–922, 921*f*
      thoracostomy tube placement for, 922–924
      thoracostomy tube removal for, 924
    suture materials and special instruments for, 925

Lower respiratory system surgery *(Continued)*
for thymic branchial cysts, 951–954
for thymomas, 951–954
for traumatic diaphragmatic hernia, 926–931
Low-fat diets, for chylothorax, 943, 943*b*, 943*t*
Low-level laser therapy, of open wounds, 189
Low-molecular-weight heparin (Dalteparin), for disseminated intravascular coagulation, 594, 638*b*
Low-profile gastrostomy tube devices, 100–101
Low-velocity forces, in fractures, 983–984
LRS (lactated Ringer's solution), 31
as wound cleanser, 184, 184*t*
L-thyroxine, for hypoparathyroidism, 615–616
L-triiodothyronine (Cytobin, Cytomel), for hypothyroidism, 615*b*
Lubrication, of instruments, 58
Lucilla sericata, for débridement, 186
Lumbar fractures, caudal. *see* Lumbosacral trauma.
Lumbar puncture, cerebrospinal fluid analysis via, 1321–1322, 1321*f*
Lumbar spine. *see* Thoracolumbar spine.
Lumbar vertebra(e), 1404–1405, 1418*f*
sacralization of, 1431
Lumbarization, of sacrum, 1431
Lumbosacral area, 1427
Lumbosacral junction, 1427, 1428*f*
Lumbosacral neoplasia, 1434–1437
definitions for, 1434
diagnosis of, 1435
clinical presentation in, 1435
imaging in, 1435, 1435*f*–1436*f*
laboratory findings in, 1435
physical examination findings in, 1435
differential diagnosis of, 1435
general considerations and clinically relevant pathophysiology, 1434
medical management of, 1436
postoperative care and assessment for, 1437
prognosis for, 1437
surgical technique for, 1436
for malignant nerve sheath tumors, 1436, 1436*b*
for tumors involving vertebral body or surrounding soft tissues, 1436
surgical treatment of, 1436
anesthesia for, 1436
positioning for, 1436
preoperative management of, 1436
surgical anatomy for, 1436
Lumbosacral stenosis, degenerative, 1431–1434
complications of, 1433
definition for, 1431
diagnosis of, 1431–1433
clinical presentation in, 1431–1432
imaging in, 1432–1433, 1432*f*
laboratory findings in, 1433
physical examination findings in, 1432
differential diagnosis of, 1433
Lumbosacral stenosis, degenerative *(Continued)*
general considerations and clinically relevant pathophysiology, 1431, 1431*f*
medical management of, 1433
prognosis for, 1433–1434
surgical technique for, 1433, 1435*f*
surgical treatment of, 1433, 1434*f*
anesthesia for, 1433
positioning for, 1433
preoperative management of, 1433
surgical anatomy for, 1433
suture materials and special instruments for, 1433
Lumbosacral trauma, 1437–1442
definitions for, 1437
diagnosis of, 1437–1438
clinical presentation in, 1437
imaging in, 1438, 1438*b*
laboratory findings in, 1438
physical examination findings in, 1437–1438
differential diagnosis of, 1438
general considerations and clinically relevant pathophysiology, 1437, 1437*f*
medical management of, 1438
postoperative care and assessment for, 1442
prognosis for, 1442, 1442*b*
surgical techniques for, 1439–1441
modified segmental spinal fixation, 1439–1440, 1441*f*
Steinmann pins/screws and polymethylmethacrylate, 1440–1441, 1441*f*–1442*f*
transilial pins, 1439, 1439*f*–1440*f*
surgical treatment of, 1438–1439
anesthesia for, 1438
positioning for, 1439
preoperative management of, 1438
surgical anatomy for, 1438, 1439*f*
suture materials/special instruments for, 1442
Lumpectomy, 746, 748
Lung(s)
healing of, 895–896
surgical anatomy of, 889, 890*f*
Lung lobe torsion (LLT), 905–907
causes of, 905*b*
clinical presentation of, 905
definition for, 905
diagnosis of, 905–906
diagnostic imaging of, 905–906, 906*f*
differential diagnosis of, 906
general considerations and clinically relevant pathophysiology, 905
laboratory findings in, 906
medical management of, 906, 906*b*
physical examination findings in, 905
postoperative care and assessment for, 907
prognosis of, 907
surgical technique for, 907
surgical treatment of, 906–907
suture materials and special instruments for, 907
Lung surgery, 884–915
anesthesia for, 884–888, 885*t*–886*t*, 886*b*–887*b*
antibiotics for, 888
complete lobectomy for, 894–895, 896*f*
complications of, 897, 897*b*
definitions for, 884
healing after, 895–896
lung biopsy for, 893–894
for lung lobe torsion, 905–907
partial lobectomy for, 894, 895*f*
for pectus excavatum, 907–912
postoperative care and assessment for, 897, 897*b*
preoperative management of, 884, 884*b*
for pulmonary abscesses, 903–905
for pulmonary neoplasia, 900–903
special age considerations for, 897
surgical anatomy for, 888–889, 889*f*–890*f*
surgical materials and special instruments for, 896–897, 896*f*
for thoracic wall neoplasia, 912–914
for thoracic wall trauma, 897–900
thoracotomy for, 889–893, 889*b*, 889*t*
Lung-digit syndrome, feline, 900
Lutalyse (prostaglandin $F_{2\alpha}$)
for pregnancy prevention or termination, 729*b*
for pyometra, 757*b*
Luteinizing hormone (LH), in females, 720–721
Luxation(s), 958*b*
carpal, 1202–1206
coxofemoral, 1220–1225
closed reduction of caudoventral luxation, 1222, 1222*f*
craniodorsal luxation, 1221, 1222*f*
definition for, 1209, 1220
diagnosis of, 1220
clinical presentation in, 1220
differential diagnosis of, 1221
imaging in, 1220, 1221*f*
laboratory findings in, 1220
physical examination in, 1220, 1220*f*–1221*f*
general considerations and clinically relevant pathophysiology, 1220, 1220*b*
medical management for, 1221–1222
closed reduction of a caudoventral luxation in, 1222, 1222*f*
closed reduction of a craniodorsal luxation, 1221, 1222*f*
Ehmer slings in, 1221–1222, 1222*f*
hind limb hobbles in, 1222, 1223*f*
prognosis for, 1225
surgical treatment for, 1223
anesthesia for, 1223
capsule reconstruction in, 1223, 1223*b*, 1224*f*
exploration of the hip joint in, 1223, 1223*b*
joint reconstruction in, 1224, 1224*f*
positioning for, 1223
postoperative care after, 1225
preoperative management of, 1223
surgical anatomy for, 1223

Luxation(s) *(Continued)*
translocation of the greater trochanter in, 1225, 1225*f*
elbow
caused by premature closure of the distal ulnar or radial physes, 1197–1200
definition for, 1197
differential diagnosis of, 1198
general considerations and clinically relevant pathophysiology, 1197–1198, 1197*b*, 1198*f*
medical management of, 1198
prognosis for, 1200
surgical treatment for, 1198
anesthesia for, 1198
complications of, 1200
positioning for, 1198
postoperative care after, 1200, 1200*b*
preoperative management of, 1198
radial lengthening for, 1199
surgical anatomy for, 1198
suture materials and special instruments for, 1199
ulnar-lengthening osteotomy for, 1198–1199, 1199*b*, 1199*f*
ulnar-shortening ostectomy for, 1199, 1199*b*, 1199*f*
congenital, 1200–1202
definition for, 1200
diagnosis of, 1200–1201
differential diagnosis of, 1201
general considerations and clinically relevant pathophysiology, 1200, 1200*f*–1201*f*
medical management for, 1201, 1201*f*
prognosis for, 1202
surgical treatment for, 1201–1202, 1201*b*
traumatic, 1193–1197
definition for, 1193
diagnosis of, 1194, 1194*f*
differential diagnosis of, 1194
general considerations and clinically relevant pathophysiology, 1193–1194, 1194*b*
medical management for, 1194, 1195*f*
prognosis for, 1197
surgical treatment of, 1194–1195, 1195*b*
anesthesia for, 1195
complications of, 1197
elbow arthrodesis for, 1196, 1196*f*, 1197*b*
open reduction for, 1195–1196, 1196*f*
positioning for, 1195
postoperative care after, 1197
preoperative management of, 1195
surgical anatomy for, 1195
suture materials and special instruments for, 1197

Luxation(s) *(Continued)*
lumbosacral, 1437–1442
patellar
lateral, 1261–1264
definition for, 1261
diagnosis of, 1261–1263
differential diagnosis of, 1263
general considerations and clinically relevant pathophysiology, 1261
medical management for, 1263
prognosis for, 1264
surgical treatment for, 1263, 1264*f*
medial, 1254–1261
definition for, 1254
diagnosis of, 1255–1256
differential diagnosis of, 1256
general considerations and clinically relevant pathophysiology, 1254–1255, 1255*f*, 1256*b*
grades of, 1256*b*
medical management of, 1256
prognosis for, 1261
surgical treatment for, 1256–1258, 1256*b*, 1257*f*
anesthesia for, 1257
arthrotomy for, 1258
lateral imbrication, tightening, and reinforcement in, 1260–1261, 1261*f*
medial release in, 1259
positioning for, 1258
postoperative care after, 1261
preoperative management of, 1257
surgical anatomy for, 1257–1258, 1257*f*
suture materials and special instruments for, 1261
tibial tuberosity transposition, 1259–1260, 1260*f*
trochlear block recession, 1258–1259, 1259*b*, 1259*f*
trochlear wedge recession, 1258, 1258*f*
sacroiliac, 1092–1095
scapular, 1172–1173
scapulohumeral joint, 1159–1167
suture repair of, 1090–1091
tarsocrural joint
physical examination findings in, 1267
surgical treatment and, 1267, 1268*f*–1269*f*, 1269
surgical treatment of, 1269, 1269*f*
tarsometatarsal, 1268, 1268*f*
treatment considerations in, 1089*b*
Lye, chemical injuries due to, 242
Lyme arthropathy, 1149–1151, 1150*b*
Lymph node(s)
location of palpable, 631, 632*f*
surgical anatomy of, 632, 632*f*
Lymph node biopsy, 633

  for vomiting after removal of gastric foreign body, 419, 419*b*
Marsupialization
  of prostatic cyst, 769–771, 770*f*
  of salivary mucocele, 358, 362, 363*f*
Masks, 42
Maspin, 531
Massage, 115–116, 116*b*, 116*f*
Masseter muscle, 1045*f*
Mast cell tumors (MCTs), of scrotum, 772–773
Mastectomy, 738
  bilateral, 746, 748
  caudal, 750*f*
  complications after, 745, 745*b*
  defined, 720
  regional, 746, 748
  simple, 746, 748
  unilateral, 746, 748
Masticatory muscle atrophy, 1325, 1326*f*
Mastitis, 748
Mastoid foramen, 1343*f*
Mathieu needle holder, 51*f*, 52
Maturation phase
  in healing of small intestine, 449
  of wound healing, 181–182
Maxilla, blood supply to, 333, 334*f*

Maxillary fractures, 1036–1047
definitions for, 1036
diagnosis of, 1036–1037, 1036*b*
differential diagnosis of, 1037
general considerations and pathophysiology of, 1036, 1037*f*
interdental stabilization techniques for, 1037–1038
interdental fixation as, 1038, 1038*f*
maxillomandibular fixation as, 1038, 1038*b*, 1038*f*
medical management of, 1037, 1037*f*
prognosis for, 1047, 1047*b*
surgical treatment for
acrylic fixators for, 1041–1042, 1041*b*, 1043*f*
anesthesia for, 1042, 1044*f*
bone plates and screws for, 1040, 1041*f*
surgical treatment of
complications of, 1047
external fixators for, 1040–1041, 1042*f*
fracture assessment score and, 1041, 1041*b*
interdental wires for, 1038, 1039*f*
interfragmentary wires for, 1038–1040, 1039*t*, 1040*f*
open reduction for, 1045
positioning for, 1043–1044
postoperative care and assessment after, 1047
preoperative management of, 1042
surgical anatomy for, 1043, 1043*b*, 1044*f*–1045*f*
surgical technique for, 1044–1047
suture materials and special instruments for, 1047
Maxillary nerve block, 151
Maxillectomy, 331
partial, 335–336, 335*f*–336*f*
Maxillomandibular fixation, for mandibular and maxillary fractures, 1038, 1038*b*, 1038*f*
Maxipime (cefepime), 80*t*
Maxon (polyglyconate) sutures, 62, 63*t*
Mayo scissors, 50, 51*f*
Mayo-Hegar needle holder, 51*f*, 52
MBC (minimum bactericidal concentration), 79
MCD. *see* Medial compartment disease.
MCT (mast cell tumors), of scrotum, 772–773
MDR (multidrug-resistant) infections, 82–83
Mean arterial pressure (MAP), 1338
Meatus, 837–838, 838*f*
Mechanical débridement, 185
Mechanical pleurodesis, 936
Medetomidine
for brain surgery, 1342
with peritonitis, 533–534
Medial buttress, 1227
Medial canthus, 268
Medial collateral ligament, 1234, 1251, 1252*f*
Medial collateral ligament injury, 1251–1252, 1253*f*
definition for, 1250–1252
diagnosis of, 1250–1251
Medial collateral ligament injury *(Continued)*
clinical presentation in, 1250
imaging in, 1251, 1251*f*
laboratory findings in, 1251
physical examination in, 1250, 1250*f*, 1251*b*
differential diagnosis of, 1251
general considerations and clinically relevant pathophysiology, 1250
medical management for, 1251
prognosis for, 1252
surgical treatment for, 1251, 1251*b*
anesthesia for, 1251, 1252*f*
positioning for, 1251
postoperative care after, 1252
preoperative management of, 1251
surgical anatomy for, 1251
suture materials and special instruments for, 1252
Medial compartment disease (MCD), 1174*t*, 1183–1186
definition for, 1183
diagnosis of, 1184, 1184*f*
differential diagnosis of, 1184
general considerations and clinically relevant pathophysiology, 1183
grading of, 1183, 1184*b*
medical management of, 1184
surgical treatment of, 1184–1185, 1185*f*–1186*f*
Medial coronoid process
exposure of
via muscle splitting, 1180, 1182*f*
via transection of the pronator teres muscle, 1180, 1181*f*
fragmented, CT of, 173*f*
removal of, 1190, 1191*f*
Medial genicular artery, 223*f*
Medial joint capsule, release of, for medial patellar luxation, 1259
Medial meniscus, 1234*f*
Medial palpebral ligament, 268
Medial patellar luxation, 1254–1261
definition for, 1254
diagnosis of, 1255–1256
differential diagnosis of, 1256
general considerations and clinically relevant pathophysiology of, 1254–1255, 1255*f*, 1256*b*
grades of, 1256*b*
medical management of, 1256
prognosis for, 1261
surgical treatment for, 1256–1258, 1256*b*, 1257*f*
anesthesia for, 1257
arthrotomy for, 1258
lateral imbrication, tightening, and reinforcement in, 1260–1261, 1261*f*
medial release in, 1259
positioning for, 1258
postoperative care after, 1261, 1262*t*
preoperative management of, 1257
surgical anatomy for, 1257–1258, 1257*f*
suture materials and special instruments for, 1261
tibial tuberosity transposition, 1259–1260, 1260*f*
Medial patellar luxation *(Continued)*
trochlear block recession, 1258–1259, 1259*b*, 1259*f*
trochlear wedge recession, 1258, 1258*f*
Medial proximal radial angle, 1081
Medial retinaculum, 1257
Median sternotomy
definition for, 884
surgical technique for, 891–893, 892*f*–893*f*
Mediastinal cysts, 951–954
clinical presentation of, 951, 951*b*
definitions for, 951
diagnosis of, 951–952
diagnostic imaging of, 952
differential diagnosis of, 952–953, 952*b*–953*b*
general considerations and clinically relevant pathophysiology, 951
history of, 952
laboratory findings in, 952
medical management of, 953, 953*b*
physical examination findings in, 952
postoperative care and assessment for, 954
prognosis of, 954
proposed staging scheme for, 951*t*
surgical technique of, 953–954, 954*b*
surgical treatment of, 953
suture materials and special instruments for, 954
Medical asepsis, 1
Medical shirts, in neurologic rehabilitation exercises, 122
Medroxyprogesterone acetate (Depo-Provera), for benign prostatic enlargement, 763–764, 764*t*
Medulla, 1324*f*
Mefoxin. *see* Cefoxitin.
Megacolon, 479–482
complications of, 482
definition for, 479
diagnosis of, 480
clinical presentation in, 480
imaging in, 480, 480*f*
laboratory findings in, 480
physical examination findings in, 480
differential diagnosis of, 480
general considerations and clinically relevant pathophysiology, 479, 479*b*
idiopathic, 479
medical management of, 480–481, 481*b*
postoperative care and assessment for, 482
prognosis for, 482
surgical technique for, 481
subtotal colectomy, 481, 481*b*
surgical treatment of, 481
anesthesia for, 481
positioning for, 481
preoperative management of, 481
surgical anatomy for, 481
suture materials and special instruments for, 481
Megavoltage radiation, for brain tumors, 1359–1360, 1360*b*
Megestrol acetate, for pregnancy prevention or termination, 729*b*

Meibomian glands, 266, 268, 273
Melanoma(s)
  digital, 262, 262*f*
  of oral cavity, 352–353, 355*b*
  of scrotum, 773
Melanosarcoma. *see* Melanoma(s).
Melena, 466
Meloxicam (Metacam), 148*t*–149*t*, 150
Membranous urethra, 684–685, 684*f*
Memory, of suture, 61*b*
Menace response, 1324–1325, 1326*f*
Meningoencephalitis
  eosinophilic, 1322
  of unknown etiology, 1453
  of unknown origin, 1453
Meningoencephalomyelitis, granulomatous, 1453
  definitions for, 1453
  diagnosis of, 1453–1454, 1454*f*
  differential diagnosis of, 1454
  general considerations and clinically relevant pathophysiology, 1453
  medical management of, 1454–1455, 1455*b*
  prognosis for, 1455
  surgical treatment of, 1455
Meniscal injury, 1243–1248
  definition for, 1243–1244
  diagnosis of, 1246
    arthroscopy in, 1246
    clinical presentation in, 1246
    imaging in, 1246
    physical examination in, 1246
  differential diagnosis of, 1246
  general considerations and clinically relevant pathophysiology, 1244–1245, 1245*b*, 1246*f*
  medical management for, 1246
  prognosis for, 1248
  surgical treatment for, 1246–1247
    anesthesia for, 1247
    exploratory arthrotomy in, 1247
    meniscal release in, 1246–1248, 1248*f*
    partial meniscectomy in, 1247, 1247*f*
    positioning for, 1247
    postoperative care after, 1248
    preoperative management of, 1247
    surgical anatomy for, 1247, 1247*f*
    suture materials and special instruments for, 1248
    transection of the meniscotibial ligament in, 1248
Meniscal tears. *see* Meniscal injury.
Menisci, 1141*f*
Mental status, 1323, 1324*t*
Mental stimulation, of neurologic patients, 122
Meperidine (Demerol, Validus, Pethidine), 127*t*–131*t*, 133
Mephyton (vitamin K_1), for extrahepatic bile duct obstruction, 571
MER (maintenance energy requirement), 90
N-(2-Mercaptopropionyl)-glycine (MPG, Tiopronin), for urinary calculi, 705*b*
Meropenem (Merrem), as drug of last resort, 82–83
Mersilene (polyester) surgical mesh, 68
Mersilene (polyester) sutures, 62, 63*t*
Mesenchymal stem cells, 968
  for bone grafting, 995
Mesenteric avulsion, 512–513, 512*b*
Mesenteric lymphangiography, 945, 945*b*
Mesenteric portography, 556, 556*f*
Mesenteric torsion. *see* Intestinal torsion.
Mesenteric volvulus. *see* Intestinal volvulus.
Mesh, synthetic surgical, 68
Mesh grafts, 236
  creation of, 236, 236*f*
  drainage of, 236
Mesocolon, 468*b*
Mesometrium, 725–726
Mesorectum, 483–484
Mestinon, for acquired myasthenia gravis, 953*b*
Metacarpal fractures and luxations, 1087–1092
  definitions for, 1087
  diagnosis of, 1087, 1087*b*
  differential diagnosis of, 1087
  general considerations and pathophysiology of, 1087
  medical management of, 1088
  prognosis for, 1092
  surgical treatment of, 1088–1090, 1088*f*–1089*f*, 1089*b*
    anesthesia for, 1089
    for avulsion fractures, 1088*f*, 1090, 1090*b*
    for comminuted fractures, 1088*f*–1089*f*, 1090, 1090*b*
    complications of, 1092
    considerations in, 1088*b*
    fracture assessment score for, 1088, 1089*b*
    positioning for, 1090
    postoperative care assessment after, 1091–1092
    preoperative management of, 1089
    surgical anatomy for, 1090, 1090*b*
    surgical technique for, 1090–1091
    suture materials and special instruments for, 1091
    for transverse fractures, 1089*f*, 1090
Metacarpal pad replacement, 263–265, 264*f*
Metallic sutures, 63
Metamucil (psyllium), after prostatic or perineal surgery, 744*b*
Metaphyseal artery, 1024*f*
Metaphyseal dysplasia, 1296–1297, 1296*b*–1297*b*, 1297*f*
Metaphyseal fractures
  femoral, 1109–1114
  humeral, 1061–1066
  radial and ulnar, 1074–1076
  tibial and fibular, 1128–1131
  trabecular bone healing of, 1028, 1030*f*
Metaphyseal osteopathy, 1296–1297, 1296*b*–1297*b*, 1297*f*
Metasplints, for temporary fracture stabilization, 982–983, 983*f*
Metastatic bone tumors, 1299
Metastatic pulmonary neoplasia, 900
Metatarsal fractures and luxations, 1087–1092
  definitions for, 1087
Metatarsal fractures and luxations *(Continued)*
  diagnosis of, 1087, 1087*b*
  differential diagnosis of, 1087
  general considerations and pathophysiology of, 1087
  medical management of, 1088

  surgical treatment of, 1088–1090, 1088*f*–1089*f*, 1089*b*
    anesthesia for, 1089
    for avulsion fractures, 1088*f*, 1090, 1090*b*
    for comminuted fractures, 1088*f*–1089*f*, 1090, 1090*b*
    complications of, 1092
    considerations in, 1088*b*
    fracture assessment score for, 1088, 1089*b*
    positioning for, 1090
    postoperative care assessment after, 1091–1092
    preoperative management of, 1089
    surgical anatomy for, 1090, 1090*b*
    surgical technique for, 1090–1091
    suture materials and special instruments for, 1091
    for transverse fractures, 1089*f*, 1090
Metatarsal pad replacement, 263–265, 264*f*
Methadone (Dolophine, Methadose, Amidon), 127*t*–131*t*, 133
Methicillin-resistant *Staphylococcus aureus* (MRSA), 82–83
Methicillin-resistant *Staphylococcus pseudintermedius* (MRSP), 83–84
Methimazole (Tapazole), for feline hyperthyroidism, 619–620, 620*b*
  preoperative, 620–621, 620*b*
Methoxypropyl cyanoacrylate tissue adhesive (Tissumend II Sterile), 191
Methylene blue, administration of, 611, 611*b*
Methylprednisolone acetate, for bicipital tenosynovitis, 1170
Metoprolol, for pheochromocytoma, 594–596
Metronidazole (Flagyl), 81*t*, 82
  for hepatic abscess, 565*b*
  for liver surgery, 543*b*
  for perianal fistula, 503, 503*b*
  for perineal, rectal, or colonic surgery, 467–468, 468*b*
  for peritonitis, 531, 531*b*
  for portosystemic shunts, 555, 555*b*
  for septic arthritis, 1140*t*
Metzenbaum, 796–797
Metzenbaum (Metz) scissors, 50, 51*f*, 796–797
Mexiletine (Mexitil)
  for cardiac disease, 789*b*
  for gastric dilatation-volvulus, 425*b*
Mexitil (mexiletine)
  for cardiac disease, 789*b*
  for gastric dilatation-volvulus, 425*b*
Mezlocillin, 80
MG. *see* Myasthenia gravis.
MIC (minimum inhibitory concentration), 79

Michel trephine, 882*f*
Michele trephine, for bone biopsy, 1302, 1303*f*
Microcore biopsy, of small intestine, 437
Microcurette, for arthroscopy, 167, 167*f*
Microfracture, for medial compartment disease, 1185, 1186*f*
Microhepatica, with congenital portosystemic shunt, 552
Microorganisms
  normal or resident skin, 36
  transmission of, 1
Microvascular flap transfer, 232–237
Midazolam
  for extrahepatic biliary surgery, 583*b*
  for pericardiocentesis, 820*b*
  for premedication, 131
  for severe dyspnea, 834*b*
Midcervical dorsal laminectomy, 1372–1373, 1373*f*
Middle colic artery, 468
Middle ear, 305, 305*f*
Middle ear polyps. *see* Inflammatory polyps.
Middle gluteal muscle, 1112*f*

    surgical treatment of, 581
  salivary, 358–363
    complications of, 363
    definitions for, 358
    diagnosis of, 358–360
      clinical presentation in, 358, 359*b*
      imaging in, 360
      laboratory findings in, 360
      physical examination findings in, 359–360, 360*b*
    differential diagnosis of, 360
    general considerations and clinically relevant pathophysiology, 358, 359*f*
    medical treatment for, 360
    postoperative care and assessment for, 363
    prognosis for, 363
    surgical techniques for, 361–363
      mandibular and sublingual salivary gland excision, 361–363, 362*f*–363*f*
      parotid gland excision, 363
      zygomatic gland excision, 363
    surgical treatment for, 360–361, 360*b*
      anesthesia for, 360–361
      positioning for, 361
      preoperative management of, 360

Mucometra, 752
Multicolor stain, on instruments, 58*t*
Multidex (maltodextrin), for wound healing, 187
Multidrug-resistant (MDR) infections, 82–83
Multifilament suture, 62, 63*t*
Multimodal analgesia, 144–151, 148*t*–149*t*
  amantadine in, 148*t*–149*t*, 151
  amitriptyline in, 148*t*–149*t*, 151
  Bier block in, 152
  brachial plexus blocks in, 152
  coccygeal epidurals in, 155
  cranial cruciate surgery local blocks in, 153
  dental blocks in, 151
  epidural catheter in, 154–155, 155*b*
  epidurals in, 153–154, 153*t*, 154*b*
  femoral/sciatic nerve blocks in, 153
  gabapentin in, 148*t*–149*t*, 151
  intercostal nerve blocks in, 152
  local, 144–150
    for regional techniques, 151–155
  maropitant in, 148*t*–149*t*, 151
  NSAIDs in, 150, 150*b*
  opioids in, 144, 149*t*
  piprants in, 150–151
  retrobulbar blocks in, 152
  RUMM nerve blocks in, 152–153
Multiple cartilaginous exostosis, 1299, 1300*t*
Multiple ligament injuries, 1252–1254
  definitions for, 1252
  diagnosis of, 1253
  differential diagnosis of, 1253
  general considerations and clinically relevant pathophysiology, 1252–1253
  medical management of, 1253
  prognosis for, 1254
  surgical treatment for, 1253–1254, 1254*f*
Multiple punctate relaxing incisions, 210, 212*f*
Muriatic acid, chemical injuries due to, 242
Muscle(s)
  healing of, 1283
  surgical anatomy of, 1281–1283, 1281*f*
  sutures for, 65
Muscle biopsy, 1460, 1461*f*
Muscle contracture
  defined, 1288–1289, 1291
  hamstring, 1292
  infraspinatus fibrotic, 1288–1289
    definitions for, 1288
    diagnosis of, 1288, 1289*f*
    differential diagnosis of, 1288–1289
    general considerations and clinically relevant pathophysiology, 1288
    medical management of, 1289
    postoperative care for, 1289
    prognosis of, 1289
    surgical treatment of, 1289
  quadriceps, 1289–1291
    definitions for, 1289
    diagnosis of, 1290, 1290*f*
    differential diagnosis of, 1290
    general considerations and clinically relevant pathophysiology, 1289–1290
Muscle contracture *(Continued)*
    medical management of, 1290
    physical rehabilitation for, 1290
    postoperative care and assessment for, 1291
    prognosis of, 1291
    surgical treatment for, 1290–1291
  semitendinosus, 1292
Muscle fiber, 1281*f*
Muscle flaps, 228–231
  caudal sartorius, 230, 230*f*
  cranial sartorius, 229–230, 230*f*
  external abdominal oblique, 229, 229*f*
  flexor carpi ulnaris, 230–231, 231*f*
  temporalis, 231, 232*f*
Muscle injury or disease, 1280–1294
  Achilles tendon rupture as, 1284–1286
  fibrotic myopathy as, 1291–1293
  infraspinatus fibrotic contracture as, 1288–1289
  muscle-tendon unit contusion and strains as, 1280–1282
  muscle-tendon unit laceration as, 1282–1284
  quadriceps contracture as, 1289–1291
Muscle release, for quadriceps contracture, 1291
Muscle-tendon unit contusion, 1280–1282
  definitions for, 1280
  diagnosis of, 1280, 1281*f*
  differential diagnosis of, 1280
  general considerations and clinically relevant pathophysiology, 1280
  medical management of, 1281
  physical rehabilitation for, 1281, 1281*b*
  prognosis of, 1282
  surgical treatment of, 1281–1282, 1281*f*
Muscle-tendon unit laceration, 1282–1284
  definition for, 1282
  diagnosis of, 1282
  differential diagnosis of, 1282
  general considerations and clinically relevant pathophysiology, 1282
  healing of, 1283
  medical management of, 1282
  physical rehabilitation for, 1282, 1284
  prognosis of, 1284
  surgical treatment of, 1282–1283
    anesthesia for, 1283
    positioning for, 1283
    postoperative care after, 1283–1284
    preoperative management of, 1282
    surgical anatomy for, 1283
    surgical technique for, 1283, 1283*f*
    suture materials and special instruments for, 1283, 1283*f*
Muscle-tendon unit strains, 1280–1282
  definitions for, 1280
  diagnosis of, 1280, 1281*f*
  differential diagnosis of, 1280
  general considerations and clinically relevant pathophysiology, 1280
  medical management of, 1281
  physical rehabilitation for, 1281, 1281*b*
  prognosis of, 1282
  surgical treatment of, 1281–1282, 1281*f*
Muscular flap gastropexy, 408–409, 409*b*, 411*f*–412*f*
Musculocutaneous vessels, 179
Musculoskeletal system, advanced imaging modalities for, 171, 172*f*–173*f*
MVD. *see* Myxomatous valvular degeneration.
Myasthenia gravis (MG), 1460–1462
  acute fulminating, 1461*b*
  definitions for, 1460
  diagnosis of, 1460–1462, 1461*b*
  differential diagnosis of, 1462
  focal, 1461*b*
  general considerations and clinically relevant pathophysiology, 1460
  generalized, 1461*b*
    Tensilon test for, 860*b*
  medical management of, 1462, 1462*b*
  prognosis for, 1462
  surgical treatment for, 1462
Mycophenolate mofetil
  for acquired myasthenia gravis, 953*b*
  for noninfectious inflammatory disease, 1455*b*
Myelography, 1313
  advantage of, 1313
  adverse event in, 1313
  for cervical disc disease, 1375, 1377*f*
  contraindications to, 1314*b*
  defined, 1313
  extradural pattern in, 1315, 1315*f*
  intradural/extramedullary pattern in, 1315, 1315*f*
  intramedullary pattern in, 1315–1316, 1315*f*–1316*f*
  normal pattern of, 1314–1315, 1315*f*
  techniques and dosages for, 1314*b*
Myelomalacia, 1316*f*
Myelopathy, degenerative, 1447–1448, 1447*b*
Mylohyoideus muscle, 338*f*, 1044*f*
Myocutaneous flaps, 226–228, 226*b*
  cutaneous trunci, 227, 227*f*
  latissimus dorsi, 227, 227*f*
  platysma, 226
  trapezius osteo-, 228, 228*f*
Myofascial trigger points, 107
Myofibrils, 1281*f*
Myofibroblasts, in wound healing, 180
Myopathy
  defined, 1289, 1291
  fibrotic, 1291–1293
  gracilis, 1291–1293
  semitendinosus, 1291–1293
Myotonic discharges, in electromyography, 1317–1318, 1317*t*
Myringotomy, 316
Myxomas, synovial, 1308
Myxomatous mitral valve disease, 798
Myxomatous valvular degeneration (MVD), 798
  diagnosis of, 798–799
  differential diagnosis for, 799
  medical management of, 799
  prognosis for, 799*b*, 801

N

Nail bed tumors, 257
Nail clipper onychectomy, 257*f*, 259
Nail pick, in surgical scrub, 44, 45*f*

Nalbuphine (Nubain), 127*t*–131*t*, 133
Naloxone, 127*t*–131*t*, 133, 148*t*–149*t*, 154
Nanocrystalline silver dressing (Acticoat), for burns, 240*f*
Nares, endoscopy of, 876, 876*f*
Nasal adenocarcinoma, 875*f*
Nasal aspergillosis, 880–883
  clinical presentation of, 880
  definitions for, 880
  diagnosis of, 880–881
  diagnostic imaging for, 880–881
  differential diagnosis of, 881
  general considerations and clinically relevant pathophysiology, 880, 880*f*
  laboratory findings in, 881, 881*b*
  medical management of, 881, 881*b*
  physical examination findings in, 880
  prognosis of, 883
  surgical treatment of, 881
    anesthesia for, 881
    postoperative care and assessment for, 882
    preoperative management of, 881
    surgical anatomy for, 881
    technique for administering clotrimazole for, 881–882, 882*f*
    trephination for, 882, 882*f*
Nasal catheters, 30–31, 30*t*, 31*b*, 31*f*
Nasal cavity
  dorsal approach to, 840, 840*f*
  rostral
    intraoral approach to, 841, 843*f*
    lateral approach to, 840–841, 842*f*
  surgical anatomy of, 838*f*
  ventral approach to, 840, 841*f*
Nasal conchae, 837–838, 838*f*, 1343*f*
Nasal flushes, 878
Nasal planum resection, 878–879, 878*b*, 879*f*
Nasal septum, 837–838, 838*f*
Nasal skin fold, 251–252, 253*f*
Nasal skin fold resection, 251–252
Nasal tumors, 874–880
  clinical presentation of, 874
  definitions for, 874
  diagnosis of, 874–877
  diagnostic imaging for, 874–876, 875*f*
  differential diagnosis of, 877
  general considerations and clinically relevant pathophysiology, 874
  histologic classification of, 874*b*
  laboratory findings in, 876–877
  medical management of, 877
  physical examination findings in, 874
  prognosis of, 880
  surgical treatment of, 877–878
    advanced imaging-guided biopsy for, 878
    anesthesia for, 877–878
    biopsy for, 878
    positioning for, 878
    postoperative care and assessment for, 879–880
    preoperative management of, 877
    rhinotomy for, 878–879
    surgical anatomy for, 878
  suture materials and special instruments for, 879
Nasoesophageal and nasogastric intubation, 94–95, 94*b*–95*b*, 95*f*
Nasolacrimal duct, 292–293
Nasolacrimal puncta, 268
Nasopharyngeal polyps. *see* Inflammatory polyps.
Nasopharyngeal turbinates, 851, 851*f*
Naxcel (ceftiofur), 80*t*
N-butyl cyanoacrylate adhesives (Vetbond, LiquiVet, GLUture), 66–67
Necrotizing cholecystitis, 571, 582
Necrotizing encephalitis, 1453
  definitions for, 1453
  diagnosis of, 1453–1454, 1454*f*
  differential diagnosis of, 1454
  general considerations and clinically relevant pathophysiology, 1453
  medical management of, 1454–1455, 1455*b*
  prognosis for, 1455
  surgical treatment of, 1455
Necrotizing leukoencephalitis, 1453
Necrotizing meningoencephalitis, 1453
Needle(s)
  sheathed, for endoscopy, 162
  surgical, 64, 65*f*
Needle biopsy, of kidney, 655
Needle guide technique, for liver biopsy, 545
Needle holders, 50–52, 51*f*
  palmed grip for, 52, 52*f*
  pencil grip for, 52, 52*f*
  thenar grip for, 52–53, 52*f*
  thumb-ring finger grip for, 52, 52*f*
Needle point, 64, 65*f*
Needle thoracentesis, 920–922, 921*f*
Negative-pressure wound therapy (NPWT), 192, 192*b*
Nelson scissors, 50
Neomycin (Biosol), 82
  for perineal, rectal, or colonic surgery, 467–468, 468*b*
  for portosystemic shunts, 555, 555*b*
Neonatal care, after cesarean section, 738, 739*f*
Neonatal resuscitation, 738, 739*f*
Neoplasia
  adrenal, 590–597
  anal, 489–493
  bladder and urethral, 707–712
  bone, 1299–1308
  cardiac, 823–825
  colorectal, 475–477
  esophageal, 385–386
  exocrine pancreatic, 613–615
  gastric, 430–433
  hepatobiliary, 566–568
  joint, 1308–1309, 1309*f*
  of lumbosacral area, 1434–1437
  mammary, 746–751
  penile and preputial, 785–786
  pituitary, 597–599
  prostatic, 763*t*, 771–772
  pulmonary, 900–903
  renal and ureteral, 673–675
  of small intestine, 455–458
  spinal
    cervical, 1396–1399
    thoracolumbar, 1420–1421, 1420*f*
Neoplasia *(Continued)*
  splenic, 645–648
  testicular and scrotal, 772–775
  thoracic wall, 912–914
  uterine, 751–752
  vaginal, 759–761
Neoral. *see* Cyclosporine.
Neorickettsia risticii, polyarthritis due to, 1149
Neoureterostomy, 650
  for ectopic ureters, 667, 668*f*
  surgical technique for, 662
Nephrectomy, 655–656, 656*b*, 656*f*
  defined, 650
  partial, 656, 657*f*
Nephroblastomas, 673
  spinal, 1420*f*
Nephrolithiasis, 669
Nephrolithotomy, 669
Nephroliths, 669
Nephroma, 673
Nephropyelostomy, 650, 658*f*
Nephrostomy, 650
Nephrostomy tube placement, 660–662
Nephrotomy, 650, 656–657, 658*f*
Nerve biopsy, 1460, 1461*f*
Nerve blocks, for onychectomy, 257–258, 259*f*
Nerve injuries, 1430, 1430*t*
Nervous system, anatomic subdivisions of, 1323, 1324*b*
Netilmicin, 82
Neural stem cells, 970
Neurapraxia, 1430, 1430*t*
Neuroactive steroids, 127*t*–131*t*, 134
Neurodermatitis, 248–249, 248*f*
  treatment of, 249
Neurodiagnostic overview, 1313–1322
  cerebrospinal fluid analysis in, 1320–1322
  electrodiagnostics in, 1316–1320
    brainstem auditory evoked response (BAER), 1318, 1318*f*
    electroencephalography as, 1318, 1318*f*
    electromyography as, 1316–1318, 1316*f*–1317*f*, 1317*t*
    motor nerve conduction velocity as, 1318–1319, 1319*b*, 1319*f*
    repetitive nerve stimulation as, 1319–1320, 1319*f*
    sensory nerve conduction velocity as, 1319
  imaging techniques in
    epidurography and diskography as, 1316
    myelography as, 1313
    radiography and contrast radiography as, 1313–1316, 1314*b*, 1314*f*
Neurofibrillary tangles (NFTs), 1444
Neurohypophysis, 599
Neuroimaging techniques
  epidurography and diskography as, 1316
  myelography as, 1313
  radiography and contrast radiography as, 1313–1316, 1314*b*, 1314*f*
Neurologic examination, 1323–1337
  attitude/posture in, 1328–1331
  cranial nerves in, 1323–1328, 1325*t*, 1326*f*

Neurologic examination *(Continued)*
gait in, 1331–1332
mental status in, 1323, 1324*t*
pain sensation (nociception) in, 1336–1337
postural reactions in, 1332–1334
spinal reflexes in, 1334–1336
Neurologic patients, rehabilitation for, 117, 123*b*
Neurologic rehabilitation exercises, 121–122
medical shirts in, 122
mental stimulation in, 122
physio ball as, 121, 121*f*
standing as, 121
tactile stimulation as, 122
tapping as, 122
tensor bandaging in, 122
treadmill gait training as, 122
weight shifting as, 122
Neuromuscular electrical stimulation (NMES), 114, 114*b*, 114*f*
Neuropathic pain, 140
Neurosurgery equipment, 54–55, 57*f*
Neurotmesis, 1430, 1430*t*
Neutering
defined, 720
early, 728, 728*b*
recommendations for, 722–723
Neutralization plates, 958*b*, 1019, 1019*f*
application of, 1022
Neutrophil, in wound healing, 180
Neutrophil count, in peritonitis, 528–529
Neutrophilic pleocytosis, 1322
Nexium. *see* Esomeprazole.
NFTs (neurofibrillary tangles), 1444
Ninety-degree transposition flaps, 218
Nitrofurazone (Furacin), for wound healing, 186
Nitroglycerin
for cardiac disease, 789*b*
for mitral regurgitation, 790*t*–791*t*
for pheochromocytoma, 594–596, 595*t*–596*t*
for thyroidectomy, 622*t*
Nitroprusside
for cardiac disease, 789*b*
for mitral regurgitation, 790*t*–791*t*
for pheochromocytoma, 594–596, 595*t*–596*t*
for thyroidectomy, 622*t*
Nitrous oxide, in liver surgery, 542
Nizoral (ketoconazole), for perianal fistula, 502–503, 503*b*
Nocardia spp., pyothorax due to, 948*t*, 949
Nociception, 1336–1337
deep, 1337, 1337*f*
excessive, 1337, 1337*f*
neuroanatomy of, 140–142, 141*f*–142*f*
neurophysiology and modulation of, 142–144, 143*b*, 144*t*, 145*f*–147*f*
spinothalamic tract for, 1336–1337, 1336*f*
superficial, 1337
Nociceptive pain, 140
Nocita, 148*t*–149*t*, 153
Nolvasan solution, as disinfectant, 20*t*
Nonabsorbable sutures, 62–64
metallic, 63
organic, 62
Nonabsorbable sutures *(Continued)*
for skin wounds, 190
synthetic, 62–64
Nonadherent dressings, 196, 196*b*
calcium/calcium-sodium alginate, 197*t*–198*t*, 199
hydrocolloids, 197*t*–198*t*, 199
hydrogel, 197*t*–198*t*, 198–199
hypertonic saline, 196–198, 197*t*–198*t*
occlusive, 196, 197*t*–198*t*
paraffin-impregnated, 196, 197*t*–198*t*
perforated polyester film with cotton, 197*t*–198*t*
petroleum-impregnated, 196, 197*t*–198*t*
polyurethane films, 196, 197*t*–198*t*
rayon/polyethylene glycol, 197*t*–198*t*
semiocclusive, 196, 197*t*–198*t*
types of, 197*t*–198*t*
Nonbarbiturate hypnotics, 134
Non-β-cell tumors, 612
Nonchromaffin paragangliomas, cardiac, 823
Nondisplaced fractures, 983–984
Nonerosive idiopathic immune-mediated polyarthritis, 1151–1152, 1151*b*–1152*b*
Nongoitrous hypothyroidism, defined, 615
Nonhemorrhagic infarcts, 1448–1450, 1450*t*, 1451*f*
Nonimmunologic acute reactions, 34
Noninfectious arthropathies, 1134, 1135*b*, 1135*t*
Noninfectious inflammatory disease, 1453–1455
definitions for, 1453
diagnosis of, 1453–1454, 1454*f*
differential diagnosis of, 1454
general considerations and clinically relevant pathophysiology, 1453
medical management of, 1454–1455, 1455*b*
prognosis for, 1455
surgical treatment of, 1455
Noninflammatory arthropathies, 1134, 1135*b*, 1135*t*
Nonrebreathing systems, 137, 137*f*–138*f*
Nonreducible fractures, 984*f*, 985
Non-self-tapping screw, 1017
Nonsteroidal anti-inflammatory drugs (NSAIDs), 150, 150*b*
gastric ulceration and erosion due to, 428
for hip dysplasia, 1211–1212, 1212*b*
for joint disease, 1139, 1139*b*, 1139*f*, 1140*t*
for orthopedic patients, 967–968, 981, 981*t*
for osteoarthritis, 1145, 1145*b*
receptor antagonist, 144
side effects of, 1139, 1139*b*

diagnosis of, 1155–1156, 1155*b*, 1156*f*
differential diagnosis of, 1156
general considerations and clinically relevant pathophysiology, 1154–1155, 1155*b*, 1155*f*
medical management of, 1156
open surgical techniques for, 1158*b*
caudal approach for, 1159
infraspinatus tenotomy for, 1158–1159
postoperative care and assessment after, 1159
surgical treatment of, 1156–1158
prognosis of, 1159
surgical treatment of, 1156–1158
of stifle, 1264–1266
definition for, 1264
diagnosis of, 1264–1265, 1265*f*
differential diagnosis of, 1265
general considerations and clinically relevant pathophysiology, 1264
medical management of, 1265
prognosis for, 1266
surgical treatment for, 1265–1266, 1265*f*
of tarsus, 1272–1277
definition for, 1272
diagnosis of, 1272
arthroscopy in, 1272, 1273*f*
clinical presentation in, 1272, 1272*b*
imaging in, 1272, 1272*b*, 1272*f*–1273*f*
physical examination in, 1272
Osteochondritis dissecans (OCD) *(Continued)*
differential diagnosis of, 1272–1274
general considerations and clinically relevant pathophysiology, 1272
medical management of, 1274
prognosis for, 1276–1277, 1277*b*
surgical treatment of, 1274
anesthesia for, 1274
arthroscopy in, 1274
arthrotomy in, 1274
dorsolateral approach to, 1275
dorsomedial approach to, 1274
plantarolateral approach to, 1275–1276, 1276*f*
plantaromedial approach to, 1274, 1275*f*
positioning for, 1274
postoperative care after, 1276
preoperative management of, 1274
surgical anatomy for, 1274
suture materials and special instruments for, 1276
Osteochondromas, tracheal, 864–865, 866*f*
Osteochondromatosis, 1299, 1300*t*
Osteochondrosis, 1154. *see also* Osteochondritis dissecans.
Osteoconduction, 991, 992*t*
Osteodystrophy, hypertrophic (types I and II), 1296–1297, 1296*b*–1297*b*, 1297*f*
Osteogenesis, 991, 992*t*
distraction, 1003, 1027–1028, 1029*f*
Osteoinduction, 991, 992*t*
Osteointegration, 991
Osteokinematics, 105
Osteomyelitis, 1032, 1033*f*, 1309–1312
acute, 1309, 1311, 1311*b*
bacterial, 1309–1310
chronic, 1309, 1311–1312
definitions for, 958*b*, 1309
diagnosis of, 1310–1311
clinical presentation in, 1310
imaging in, 1310, 1310*f*
laboratory findings in, 1311, 1311*b*
physical examination findings in, 1310, 1310*f*
differential diagnosis of, 1311
fracture-associated, 1309–1310
general considerations and clinically relevant pathophysiology, 1309–1310, 1309*b*
hematogenous, 1309–1310
juvenile, 1295–1296, 1295*b*–1296*b*, 1296*f*
medical management of, 1311
mycotic, 1310
postoperative care and assessment for, 1312
posttraumatic, 1309–1310
prognosis for, 1312
surgical technique for, 1311–1312
surgical treatment of, 1311
anesthesia for, 1311
positioning for, 1311
preoperative management of, 1311
surgical anatomy for, 1311
suture materials and special instruments for, 1312
of young German shepherds, 1295–1296, 1295*b*–1296*b*, 1296*f*

Osteopathy
craniomandibular, 1298–1299, 1299*b*, 1299*f*
hypertrophic, 1297–1298, 1298*f*
metaphyseal, 1296–1297, 1296*b*–1297*b*, 1297*f*
Osteophytosis, 1134
Osteosarcoma, 1299, 1300*t*
advanced imaging modalities for, 178, 178*f*
of appendicular skeleton, 1300*t*
of axial skeleton, 1300*t*
in cats, 1300, 1300*t*
distal radial, limb-sparing procedure for, 1305
in dogs, 1299, 1300*t*
imaging of, 1301, 1301*f*
metastases of, 1299
of oral cavity, 354
of thoracic wall, 912
Osteosynthesis
bridging, 986
minimally invasive percutaneous, 1023
Osteotomes, 54–55, 56*f*
Osteotomy(ies), 1033–1035
apophyseal, 958*b*, 1033
closing wedge, 1034–1035, 1034*f*
corrective, 1033
for deformities, 1034–1035, 1034*f*
indications for, 1034*t*
for joint incongruity, 1035, 1035*f*
corrective, defined, 958*b*
defined, 958*b*, 1197
lengthening, 1035
opening wedge, 1034–1035, 1034*f*
release, 1035
tibial plateau leveling, 1035*f*
for cranial cruciate ligament rupture, 1232, 1233*f*, 1238–1240
radiographic assessment for, 1238–1239, 1238*f*–1239*f*, 1239*t*
surgical technique for, 1239–1240, 1240*f*–1242*f*
tibial wedge
for cranial cruciate ligament rupture, 1232–1233, 1233*f*, 1240–1241
radiographic assessment for, 1240, 1242*f*
surgical technique for, 1240–1241, 1243*f*
transverse, 1034–1035
triple pelvic, 1035*f*
trochanteric, for approach to acetabulum, 1100, 1101*f*
Ostium primum, 813
Ostium secundum, 813, 813*f*
Otitis externa, 312–316
complications of, 316
definition for, 302, 312
diagnosis of, 314
clinical presentation in, 314
imaging in, 314, 314*f*
laboratory findings in, 314
physical examination findings in, 314, 314*b*
differential diagnosis of, 314–315, 315*b*
general considerations and clinically relevant pathophysiology, 312–314
Otitis externa *(Continued)*
medical management of, 315, 315*b*
anesthesia for, 315
positioning for, 315
preoperative management of, 315
surgical anatomy for, 315
surgical treatment in, 315
postoperative care and assessment in, 315–316
prognosis for, 316
surgical technique for, 315
suture materials and special instruments for, 315
Otitis interna, 316–319
definition for, 302, 316
diagnosis of, 317–318
clinical presentation in, 317
imaging in, 317–318, 317*f*–318*f*
laboratory findings in, 318
physical examination findings in, 317, 317*b*
differential diagnosis of, 318
general considerations and clinically relevant pathophysiology, 316, 316*b*
medical management of, 319
prognosis for, 319
surgical technique for, 319
surgical treatment of, 319, 319*b*
anesthesia for, 319
positioning for, 319
preoperative management of, 319
surgical anatomy for, 319
suture materials and special instruments for, 319
Otitis media, 316–319
definition for, 302, 316
diagnosis of, 317–318
clinical presentation in, 317
imaging in, 317–318, 317*f*–318*f*
laboratory findings in, 318
physical examination findings in, 317, 317*b*
differential diagnosis of, 318
general considerations and clinically relevant pathophysiology, 316
medical management of, 319
prognosis for, 319
surgical technique for, 319
surgical treatment of, 319, 319*b*
anesthesia for, 319
positioning for, 319
preoperative management of, 319
surgical anatomy for, 319
suture materials and special instruments for, 319
Otoliths, 316
Otoscopic examination, 302
Outer layer, of wound dressing, 201
Outflow, in arthroscopy, 158
Ovarian arteries, 725–726
Ovarian cystadenocarcinoma, 728*f*
Ovarian cysts, 728*f*
Ovarian pedicle, 725–726
Ovariectomy (OVE), 728–730, 728*f*, 729*b*, 731*f*–732*f*
alternatives to, 728–729, 729*b*
defined, 720
laparoscopic-assisted, 730–732, 732*f*
Ovariectomy (OVE) *(Continued)*
Miller's knot or clove hitch in, 728–729, 729*f*
Ovariohysterectomy (OHE), 728–730, 728*f*, 729*b*, 731*f*–732*f*
alternatives to, 728–729, 729*b*
cesarean section with, 736–737
cesarean section without, 737–738, 737*f*–738*f*, 738*b*
complications after, 744–745, 745*b*
defined, 720
laparoscopic-assisted, 730–732, 732*f*
Miller's knot or clove hitch in, 728–729, 729*f*
for vaginal prolapse, 760
Ovary(ies), 725–726
Ovary-sparing surgery, defined, 720
OVE. *see* Ovariectomy.
"Over the wire" esophageal dilation balloons, 162
Overlapping flap technique, for cleft palate repair, 344–345, 345*f*–346*f*
Over-the-needle catheter, for thoracentesis, 920–921, 921*f*
Oviduct, 725–726
Oxazolidinone linezolid (Zyvox), as drugs of last resort, 82–83
Oxazolidinone telithromycin (Ketek), as drugs of last resort, 82–83
Oxygen, supplemental, for brain surgery, 1339
Oxygen cage, 30*t*, 31
Oxygen tent, 29–30, 30*f*
Oxygen therapy, 29–31, 29*b*
methods for, 30*t*
face mask delivery of, 29–30, 30*t*
flow-by, 29, 30*f*, 30*t*
tent or Elizabethan collar canopy for, 30*t*
via nasal catheters, 30–31, 30*t*, 31*b*, 31*f*
via oxygen cage, 30*t*, 31
Oxyglobin, 32*t*
Oxymorphone, 127*t*–131*t*, 133
for extrahepatic biliary surgery, 583*b*
for pericardiocentesis, 820*b*
Oxytocin, to initiate uterine contraction, 738, 738*b*

P

Pacemaker implantation, for bradycardia
anesthesia for, 829, 829*b*
electrode placement in, 829, 831*f*
midline celiotomy in, 829
positioning for, 829
postoperative care and assessment in, 830–831
preoperative management of, 829
surgical treatment of, 829
suture materials and special instruments for, 829–830, 831*f*
technique for, 829, 829*b*
Pacing electrode, for bradycardia, 828
Packaging materials, for surgical packs
based on device type, 11–12, 12*t*
sterilization method, 8–9, 9*t*
Packed cell volume (PCV), 31
Packed red blood cells, 32*t*, 33

$PaCO_2$ (arterial CO_2 partial pressure), after cardiac surgery, 797
Pain
  characteristics of, 144, 144*t*
  inflammatory, 140
  neuropathic, 140
  nociceptive, 140
  pathologic or maladaptive, 140
  referred, 143–144
  signs of, 140, 141*b*
Pain Buster/ON-Q, for ear surgery, 302, 303*b*
Pain management, 140–157
  Colorado Acute Pain Scale for, 144, 146*f*–147*f*
  Glasgow Composite Pain Scale for, 144, 145*f*
Pain scales
  Colorado Acute Pain Scale, 144, 146*f*–147*f*
  Glasgow Composite Pain Scale, 144, 145*f*
Pain scoring system, 107
Pain sensation, 1336–1337
  deep, 1337, 1337*f*
  excessive, 1337, 1337*f*
  spinothalamic tract for, 1336–1337, 1336*f*
  superficial, 1337
Palatal defects. *see* Oronasal fistula(e).
Palate, primary *vs*. secondary, 342
Palatine arteries, 333, 334*f*
  major, 333, 334*f*
  minor, 333, 334*f*
Palmed grip, 52, 52*f*
Palpation-guided biopsy, of prostate, 742
Palpebral conjunctiva, 281–282
Palpebral fissure, 268
Palpebral reflex, 1325, 1326*f*–1327*f*
Pancarpal arthrodesis, 1205, 1205*f*
  defined, 1202
  with external fixator, 1205
Pancreas
  abscesses and pseudocysts of, 606–609
  endocrine function of, 604
  exocrine function of, 604
  exocrine neoplasia of, 613–615
    definitions for, 613
    diagnosis of, 614, 614*b*
    differential diagnosis of, 614
    general considerations and clinically relevant pathophysiology, 614, 614*b*
    medical management of, 614
    prognosis for, 615
    surgical treatment of, 614, 615*f*
  gastrinomas of, 612–613
  healing of, 605
  insulinomas of, 609–612
  surgery of, 599–615
    anesthesia for, 600, 600*b*
      in compromised patient, 602*t*–603*t*
      in stable patient, 601*t*–602*t*
    antibiotics for, 600
    complications of, 606
    definitions for, 599–600
    intraoperative considerations for, 601*t*–603*t*
    postoperative care and assessment in, 601*t*–603*t*, 605–606
Pancreas *(Continued)*
    preoperative management of, 600, 600*b*, 601*t*–603*t*
    special age considerations for, 606
    surgical anatomy for, 603–604, 603*b*, 604*f*
    suture materials and special instruments for, 605
    techniques for, 604–605, 604*b*
      laparoscopic pancreatic biopsy as, 604
      partial pancreatectomy as, 605, 605*b*, 605*f*–606*f*
      surgical pancreatic biopsy as, 604
Pancreatectomy
  defined, 599–600
  partial, 604–605, 605*b*, 605*f*–606*f*
Pancreatic abscess, 606–609
  definitions for, 606–607
  diagnosis of, 607–608, 607*f*, 608*b*
  differential diagnosis of, 608
  general considerations and clinically relevant pathophysiology, 607, 607*b*, 607*f*
  medical management of, 608
  prognosis for, 609
  surgical treatment of, 608, 609*b*
Pancreatic adenocarcinomas, 613
Pancreatic β-cell adenomas, 609
Pancreatic β-cell tumors. *see* Insulinomas.
Pancreatic biopsy, 604
  laparoscopic, 604
  surgical, 604
Pancreatic cysts. *see* Pancreatic pseudocysts.
Pancreatic disease, anesthesia with, 600, 601*t*–603*t*
Pancreatic duct, 604
Pancreatic enzymes, for exocrine pancreatic insufficiency, 606, 606*b*
Pancreatic insufficiency, exocrine, 606, 606*b*
Pancreatic islets, adenocarcinomas of. *see* Insulinomas.
Pancreatic pseudocysts, 606–609
  definitions for, 606–607
  diagnosis of, 607–608, 607*f*, 608*b*
  differential diagnosis of, 608
  general considerations and clinically relevant pathophysiology, 607, 607*b*, 607*f*
  medical management of, 608
  prognosis for, 609
  surgical treatment of, 608, 609*b*
Pancreatic tumors, 614
Pancreatitis
  antibiotics for, 600
  imaging of, 607–608, 607*f*
  postoperative care and assessment for, 605–606
  preoperative management of, 600
Pancrezyme, for exocrine pancreatic insufficiency, 606*b*
Panniculus reflex, 1336, 1336*f*
Panosteitis, 1295–1296, 1295*b*–1296*b*, 1296*f*
Pantoprazole (Protonix)
  for benign gastric outflow obstruction, 426*b*
  for gastric ulceration and erosion, 429, 429*b*
  for gastrinomas, 613*b*
PAO_2 (alveolar oxygen tension), after cardiac surgery, 797
PaO_2 (arterial oxygen tension), after cardiac surgery, 797
Paper, for surgical pack wrapping, 12*t*
Paper pouches, for surgical pack wrapping, 12*t*
Papillomas, oral, 356
Parachlorometaxylenol (PCMX), for surgical scrub, 46*t*
Paraconal interventricular branch, 800–801, 800*f*
Paracostal celiotomy, 517
  abdominal wall closure and, 518
Paracostal hernia, 519, 519*f*
  surgical techniques for, 521
Paraffin-impregnated (Jelonet) dressing, 196, 197*t*–198*t*
Paraganglioma. *see also* Pheochromocytomas.
  defined, 590
  nonchromaffin, cardiac, 823
Paralysis, 1332
  tick, 1464
Paranasal sinuses
  dorsal approach to, 840
  surgical anatomy of, 837–838
Paraneoplastic hypercalcemia
  signs of, 490, 490*b*
  treatment of, 491, 491*b*
Paraneoplastic hypercalcemia, differential diagnosis of, 626*b*
Paraparesis, 1332, 1404
Paraphimosis, 779–785
  complications of, 784–785
  definition for, 779
  diagnosis of, 780
  differential diagnosis of, 780
  general considerations and clinically relevant pathophysiology, 780, 781*f*
  medical management of, 781
  prognosis for, 785
  recurrent, 781*b*

tibial tuberosity transposition, 1259–1260, 1260*f*
trochlear block recession, 1258–1259, 1259*b*, 1259*f*
trochlear wedge recession, 1258, 1258*f*
Patellar reflex, 1335–1336, 1335*f*
Patellar tendon, 1112*f*
Patent ductus arteriosus (PDA), 801–805
classification of, 802*b*
complications of, 805
definitions for, 801
diagnosis of, 801–802, 802*b*
differential diagnosis of, 802
general considerations and clinically relevant pathophysiology, 801, 801*b*
medical management of, 802
prognosis of, 805
surgical treatment of, 802–804
Amplatzer Vascular Plugs and Amplatzer Canine Duct Occluder, 802–803, 803*f*
anatomy in, 804
anesthesia for, 804
intravascular coils for, 802, 803*f*
Jackson-Henderson approach to, 804–805
positioning for, 804
postoperative care and assessment for, 805
preoperative management of, 803
standard approach for, 804, 804*f*–805*f*
suture materials and special instruments for, 805
technique for, 804–805
Pathologic fracture, definition for, 976
Pathologic or maladaptive pain, 140
Patient preparation room, daily cleaning of, 24–25, 24*b*
Patient stabilization, 27–29, 27*b*, 29*b*, 29*f*
Paw(s)
exclusion from surgical area of, 37, 37*f*
surgery of, 255–265
biopsy as, 255–257, 256*f*
deep digital flexor tenectomy as, 260, 261*f*
dewclaw removal as, 260–262
digit amputation as, 262, 262*f*–263*f*
for footpad injuries, 263–265
fusion podoplasty as, 265
onychectomy (declawing) as, 257–260
Paw bandage, 204, 206*f*
Paw salvage, 263–265, 264*f*
PCM (protein-calorie malnutrition), 90
causes of, 90
consequences of, 90
diagnosis of, 90, 91*b*
PCMX (parachlorometaxylenol), for surgical scrub, 46*t*
pCO_2 (transcutaneous carbon dioxide) monitoring, to assess skin viability, 189–190
PCT (procalcitonin), in peritonitis, 528–529
PCV (packed cell volume), 31
PD (proton density) sequencing, 169
PDA. *see* Patent ductus arteriosus.
PDH. *see* Pituitary-dependent hyperadrenocorticism.
PDS II (polydioxanone) sutures, 62, 63*t*
Pectineus muscle, 520*f*, 524*f*, 527*f*
Pectus carinatum, 907
Pectus excavatum, 907–912
clinical presentation of, 907–908
definitions for, 907
diagnosis of, 907–909
diagnostic imaging of, 908–909, 909*f*
differential diagnosis of, 909
frontosagittal and vertebral indexes of, 908, 908*b*, 908*t*
general considerations and clinically relevant pathophysiology, 907, 907*f*
history of, 908, 908*b*, 908*f*
laboratory findings of, 909
medical management of, 909
physical examination findings in, 908, 908*b*
surgical treatment of, 909–910, 909*f*
anesthesia for, 910, 910*t*–911*t*
complications with, 912
positioning for, 910
postoperative care and assessment for, 911
preoperative management of, 909
prognosis of, 912
surgical anatomy for, 910
surgical technique for, 911, 911*f*–912*f*
suture materials and special instruments for, 911
Pedal lymphangiography
diagnostic, 636–637, 636*f*
surgical technique with direct, 637, 637*f*
Pedicle, 1405*f*
Pedicle flaps, 217–232
advancement, 218
bilateral (bipedicle, H-plasty), 215, 216*f*

Pedicle flaps *(Continued)*
for square and rectangular defects, 215, 216*f*
unilateral (single-pedicle), 216*f*
axial pattern, 222–226, 223*f*
caudal auricular, 222–223
caudal superficial epigastric, 224–225, 225*b*, 225*f*
cranial superficial epigastric, 225
deep circumflex iliac, 225
defined, 217, 222
direct cutaneous vessels used in, 222–223, 223*f*
genicular, 225
lateral caudal, 226
lateral thoracic, 224
omocervical (superficial cervical), 223–224
reverse saphenous conduit, 225–226, 226*f*
superficial brachial, 224
superficial temporal artery, 223
thoracodorsal, 224, 224*b*, 224*f*
interpolation, 218
pouch and hinge, 218–221, 221*f*
rotational, 218
for square and rectangular defects, 215, 216*f*
for triangular defect, 215, 215*f*
subdermal plexus, 217
transposition, 218
for square and rectangular defects, 215, 216*f*
tubed, 221–222, 222*f*
V-to-Y plasty, 210, 212*f*
Pediculectomy, 1404, 1408, 1408*f*
Peel-back pouches, opening of, 16, 16*f*
PEG (percutaneous endoscopic gastrostomy), tube placement, 97–98
PEG (polyethylene glycol), for cervical spine surgery, 1366
Pelvic fractures, 1092–1102
definitions for, 1092
diagnosis of, 1092
differential diagnosis of, 1092
general considerations and pathophysiology of, 1092
medical management of, 1092–1093
prognosis for, 1095
surgical treatment of, 1093
anesthesia for, 1093
complications of, 1095
positioning for, 1093
postoperative care and assessment after, 1094–1095
preoperative management of, 1093
stabilization using screw for, 1094, 1094*f*
surgical anatomy for, 1093, 1093*f*
surgical approach for, 1093–1094, 1093*f*
suture materials and special instruments for, 1094
Pelvic limb withdrawal reflex, 1335–1336
Pelvic nerve, 689*f*, 726–727, 727*f*
Pelvic osteotomy, 1212, 1215–1216, 1216*b*, 1216*f*
Pelvic urethra, 684–685, 684*f*
Pencil grip, 52, 52*f*
Penetrating trauma, oropharyngeal, 363–365
complications of, 365
definition for, 363
diagnosis of, 364
clinical presentation in, 364
history in, 364
imaging in, 364, 364*f*–365*f*
laboratory findings in, 364
physical examination findings in, 364
differential diagnosis of, 364
general considerations and clinically relevant pathophysiology, 363–364
postoperative care and assessment for, 365
prognosis for, 365
surgical techniques for, 364–365, 365*f*
surgical treatment for, 364
anesthesia for, 364
preoperative management of, 364
surgical anatomy for, 364
Penetrating wound, 183, 183*b*
D-Penicillamine (Cuprimine), for urinary calculi, 705*b*
Penicillinase inhibitors, 80
Penicillins, 80
Penile amputation
partial, for paraphimosis, 783–784, 783*f*
subtotal, for hypospadias, 776, 778*f*
Penile lacerations, 786
Penile punctures, 786
Penile trauma and neoplasia, 785–786
complications of, 786
definitions for, 785
diagnosis of, 785–786
differential diagnosis of, 786
general considerations and clinically relevant pathophysiology, 785, 785*b*, 785*f*
medical management of, 786
prognosis for, 786
surgical treatment of, 786
Penile urethra, 684–685, 684*f*
Penis
anatomy of, 727, 727*b*
physical examination of, 722
Penrose drain, 191, 191*f*
Pentastarch, 32*t*
Peracetic acid sterilization, 5*t*, 9
Percutaneous balloon valvuloplasty, for pulmonic stenosis, 806
Percutaneous endoscopic gastrostomy (PEG), tube placement, 97–98
Percutaneous gastrostomy tube placement
blind, 98, 99*f*
endoscopic, 97–98
with gastropexy, 98, 100*f*
low-profile, 100–101
mid-line laparotomy, 98
Percutaneous liver biopsy, 544–545
blind, 545
false-negative results in, 545*b*
fine-needle aspiration and, 545
sedation for, 545
tissue core, 544, 544*f*
ultrasound-guided, 545
Perforated polyester film with cotton dressing, 197*t*–198*t*
Perianal fissures. *see* Perianal fistulae.
Perianal fistulae, 501–504
complications of, 504, 504*b*
definition for, 501
diagnosis of, 501–502
clinical presentation in, 501
imaging in, 502
laboratory findings in, 502
physical examination findings in, 501–502, 502*b*, 502*f*
general considerations and clinically relevant pathophysiology, 501
medical management of, 502–503, 502*b*–503*b*
postoperative care and assessment for, 504
prognosis for, 504
surgical technique for, 504
surgical treatment of, 503–504
anesthesia for, 504
positioning for, 504
preoperative management of, 504
surgical anatomy for, 504
Perianal glands, 489
Perianal sinuses. *see* Perianal fistulae.
Pericardial cavity, 821
Pericardial constriction, 817–823
definitions for, 817
diagnosis of, 818–819
clinical presentation of, 818
echocardiography in, 819
electrocardiogram in, 818, 818*f*
history in, 818
imaging in, 818–819, 818*f*
laboratory findings in, 819, 819*b*
physical examination findings in, 818
signalment in, 818
differential diagnosis of, 819
general considerations and clinically relevant pathophysiology, 817–818
medical management of, 819–820, 820*b*
prognosis for, 823
surgical treatment of, 820–821
Pericardial diaphragmatic hernia. *see* Peritoneopericardial diaphragmatic hernia.
Pericardial effusion, 817–823
definitions for, 817
diagnosis of, 818–819
clinical presentation of, 818
echocardiography in, 819
electrocardiogram in, 818, 818*f*
history in, 818
imaging in, 818–819, 818*f*
laboratory findings in, 819, 819*b*
physical examination findings in, 818
signalment in, 818
differential diagnosis of, 819
general considerations and clinically relevant pathophysiology, 817–818
medical management of, 819–820, 820*b*
prognosis for, 823
surgical treatment of, 820–821
Pericardial fluid, 821
Pericardial tamponade. *see* Cardiac tamponade.

Pericardiectomy, 820–821
  for chylothorax, 944
  subphrenic (subtotal), via right thoracotomy, 821, 822*f*
  thoracoscopic, 821–822, 823*f*
  total, 821
Pericardiocentesis, 819, 820*b*
Pericarditis
  constrictive. *see* Pericardial constriction.
  infectious, 817
Pericardium, 817
  surgical anatomy of, 795, 821
Perimedullary mesh, 1350–1351
Perimysium, 1281–1282, 1281*f*
Perineal castration, 734
Perineal fistulae. *see* Perianal fistulae.
Perineal hernia, 496–501
  complications of, 500–501, 501*b*
  definition for, 496
  diagnosis of, 497–498
    clinical presentation in, 497
    imaging in, 497–498, 498*f*
    laboratory findings in, 498
    physical examination findings in, 497, 497*b*
  differential diagnosis of, 498
  general considerations and clinically relevant pathophysiology, 496–497, 497*b*, 497*f*
  medical management of, 498
  postoperative care and assessment for, 500
  prognosis for, 501
  surgical techniques for, 499–500
    approach for, 499–500, 499*b*, 499*f*
    ductus deferopexy, 500
    internal obturator transposition herniorrhaphy, 500, 500*f*
    traditional (anatomic) herniorrhaphy, 499–500
  surgical treatment of, 498–499, 498*b*
    anesthesia for, 499
    positioning for, 499
    preoperative management of, 498–499
    surgical anatomy for, 499, 499*b*
Perineal reflex, 1336, 1336*f*
Perineal urethrostomy
  canine, 689–690, 692*f*
  feline, 690–692, 693*f*
Perineal urethrotomy, 688, 690*f*–691*f*
Perinephric abscesses. *see* Perirenal abscesses.
Perineum, 482–510
  anesthetic considerations for, 483
  antibiotics for, 483
  complications of, 489, 489*b*
  definitions for, 482
  hernia of, 496–501
  postoperative care and assessment for, 488–489
  preoperative concerns for, 482–483, 482*b*
  special age considerations for, 489
  surgical anatomy of, 483–484, 484*b*
  surgical techniques for, 484–487
    anal sacculectomy, 487, 487*b*
    rectal resection, 484–487
  suture materials and special instruments for, 488
Periodontitis, 1036
Periosteal arteries, 1024*f*
Periosteal elevators, 54–55, 55*f*
Periostitis, mandibular, 1298–1299, 1299*b*, 1299*f*
Peripheral nervous system (PNS) disorders, 1460–1464
  acquired myasthenia gravis, 1460–1462, 1461*b*
  acute idiopathic polyradiculoneuritis, 1463–1464
  autoimmune polymyositis as, 1462–1463
  muscle and nerve biopsy for, 1460
  tick paralysis, 1464
Peripheral parenteral nutrition (PPN), 90
Periprostatic cysts, 768, 769*f*
Perirenal abscesses, 675–677
  complications of, 677
  definitions for, 675
  differential diagnosis of, 676
  general considerations and pathophysiology of, 676
  medical management of, 676
  postoperative care and assessment for, 677
  prognosis of, 677
  special age considerations for, 677
  surgical technique for, 677
  surgical treatment of, 676
  suture materials and special instruments for, 677
Peritoneal lavage, 531, 534, 534*b*, 534*f*
Peritoneopericardial diaphragmatic hernia (PPDH), 931–933
  clinical presentation of, 931–932
  definition for, 931
  diagnosis of, 931–932
  diagnostic imaging of, 932, 932*f*
  differential diagnosis of, 932
  general considerations and clinically relevant pathophysiology, 931, 931*b*, 931*f*
  medical management of, 932
  physical examination findings in, 932
  postoperative care and assessment of, 933
  prognosis of, 933
  radiographic signs of, 932*b*
  surgical technique for, 933
  surgical treatment of, 932–933
  suture materials and special instruments for, 933
Peritoneum, 513*f*
Peritonitis, 527–535
  bile, 528, 581–584
    definition for, 581
    diagnosis of, 581, 582*b*
    differential diagnosis of, 582–583, 583*b*
    general considerations and clinically relevant pathophysiology, 582, 582*b*
    medical management of, 583
    prognosis for, 584
    surgical treatment of, 583, 583*b*
  definitions for, 527
  diagnosis of, 528–530, 529*f*–530*f*, 530*b*
  differential diagnosis of, 530
  general considerations and clinically relevant pathophysiology, 527–528
Peritonitis *(Continued)*
  hepatic necrosis due to, 533
  hypotension and, 532, 533*b*
  medical management of, 530–531
    antibiotics in, 531, 531*b*
    heparin in, 531, 531*b*
    intravenous potassium supplementation in, 530–531, 530*t*
    sodium bicarbonate in, 530–531, 530*b*
    tamoxifen for, 531
  postoperative, antibiotics for, 449–450, 449*b*
  primary, 527
  primary generalized, 527
  prognosis for, 535
  sclerosing encapsulating, 527–528
  secondary generalized, 527
  septic, 528–529
  surgical treatment for, 531–534
    abdominocentesis in, 531, 534
    anesthesia for, 532–534, 532*b*–533*b*
    closed-suction drainage in, 534–535, 535*f*
    diagnostic peritoneal lavage in, 531, 534, 534*b*, 534*f*
    exploratory surgery in, 532, 534
    open abdominal drainage in, 532, 534–535
    postoperative care and assessment in, 535
    preoperative management of, 532
    suture materials and special instruments for, 535
Permafoam (polyurethane foam dressings), 197*t*–198*t*, 199
Perma-Hand (silk sutures), 63*t*
Peroneal nerve biopsy, 1461*f*
Persistent fourth right aortic arch, 394. *see also* Vascular ring anomalies.
Personnel, on surgical team, 23
PET (positron emission tomography), physics of, 170–171, 171*f*
PET/CT (positron emission tomography/computed tomography), physics of, 171
Petroleum products, chemical injuries due, 242
Petroleum-impregnated (Adaptic) dressing, 196, 197*t*–198*t*
Petroleum-impregnated with bismuth tribromophenate (Xeroform), 196, 197*t*–198*t*
$PGF_{2\alpha}$ (prostaglandin $F_{2\alpha}$)
  for pregnancy prevention or termination, 729*b*
  for pyometra, 757*b*
pH, normal, 917*t*
Phalangeal fractures and luxations, 1087–1092
  definitions for, 1087
  diagnosis of, 1087, 1087*b*
  differential diagnosis of, 1087
  general considerations and pathophysiology of, 1087
  medical management of, 1088
  prognosis for, 1092

Phalangeal fractures and luxations *(Continued)*
surgical treatment of, 1088–1090, 1088*f*–1089*f*, 1089*b*
anesthesia for, 1089
complications of, 1092
fracture assessment score for, 1088, 1089*b*
positioning for, 1090
postoperative care assessment after, 1091–1092
preoperative management of, 1089
surgical anatomy for, 1090, 1090*b*
surgical technique for, 1090–1091
suture materials and special instruments for, 1091
Phallopexy, 779, 784, 784*f*
"Phantom scratching", 1355
Pharyngeal mucocele, 358, 359*f*, 360*b*
Pharyngeal mucosal flaps, bilateral, for soft palate hypoplasia repair, 345
Pharyngoscopy, for brachycephalic syndrome, 853
Pharyngostomy tubes, 94
Pharyngotomy, 340
Pharyngotomy incision, endotracheal tube placement through, 1042, 1044*f*
Phase coherence, 169
Phase-contrast MRI, 170
Phenobarbital, for brain surgery, 1339*t*
Phenol, chemical injuries due, 242
Phenothiazines, for premedication, 125, 126*b*, 127*t*–131*t*
acepromazine as, 125
Phenoxybenzamine (Dibenzyline)
to improve urination, 701*t*
for pheochromocytoma, 594–596, 595*t*–596*t*
Phenserine, for cognitive dysfunction syndrome, 1445–1447
Phentolamine, for pheochromocytoma, 594–596, 595*t*–596*t*
Phenylephrine
for cardiac disease, 789*b*
for peritonitis, 533, 533*b*
for pheochromocytoma, 594–596, 595*t*–596*t*
Phenylpropanolamine (PPA)
for urinary incontinence, 713, 714*b*, 746*b*
for urinary sphincter leakage, 666*b*
Pheochromocytomas
anesthetic considerations for, 594–596, 595*t*–596*t*
defined, 590
diagnosis of, 590–592
history of, 591
physical examination in, 591
differential diagnosis of, 598
general considerations and clinically relevant pathophysiology, 590
intraoperative considerations for, 595*t*–596*t*
medical management of, 598
postoperative management of, 595*t*–596*t*
preoperative management of, 594, 595*t*–596*t*
Phimosis, 777–779
definitions for, 777
diagnosis of, 777
differential diagnosis of, 778
general considerations and clinically relevant pathophysiology, 777
medical management of, 778
prognosis for, 779
surgical treatment of, 778–779, 778*b*, 779*f*–780*f*
Phonophoresis, 112–113
Phosphorus
chemical injuries due, 242
high, 28*t*
low, 28*t*
Phrenic nerves, 795
Phrenicoabdominal veins, 556
Phrenicoabdominal vessels, 587, 587*f*
Phycomycosis, 430
Physeal bone healing, 1028, 1031*f*
Physeal closure, premature radial and ulnar, 1079
Physeal fractures, 984, 984*b*, 985*f*
femoral, 1114–1118
healing of, 1028, 1031*f*
humeral, 1061–1066
radial and ulnar, 1077–1079
tibial and fibular, 1131–1133
Physeal resection, partial, 1082, 1082*f*
Physical examination, 26, 27*t*
Physical rehabilitation, 105–124
for Achilles tendon rupture, 1286
after cranial cruciate ligament rupture extracapsular repair, 1245*t*
after femoral head and neck osteotomy, 1219*t*
after joint surgery, 123, 123*b*
after total hip replacement, 1218*t*
benefits of, 105, 106*b*
developing rehabilitation plan for, 109, 110*t*
evaluation of, 106–109, 106*b*
body condition scoring systems for, 107, 107*b*, 108*f*–109*f*
girth measurement for, 106, 107*f*
goniometer for, 107–109, 109*f*, 109*t*
lameness scoring for, 106–107, 107*b*
pain scoring system for, 107
exercise physiology in, 105–106
for fractures, 123, 123*b*
acetabular, 1101
femoral
diaphyseal and supracondylar, 1110*t*
metaphyseal and articular, 1110*t*, 1114
physeal, 1110*t*, 1118
humeral articular, physeal, and metaphyseal, 1065, 1067*t*
humeral diaphyseal and supracondylar, 1059–1060
iliac, ischial, and pubic, 1098–1099
metacarpal, metatarsal, phalangeal, and sesamoid, 1091–1092
patellar, 1120
radial and ulnar
growth deformities, 1083
metaphyseal and articular, 1076
physeal, 1078–1079
Physical rehabilitation *(Continued)*
radial or tibial diaphyseal, 1072
sacroiliac, 1094–1095
scapular fractures, 1052, 1053*t*
tibial and fibular
diaphyseal, 1128
metaphyseal and articular, 1130
physeal, 1133
general considerations for, 110–117
for joint disease, 1143
for muscle contracture
infraspinatus, 1289
quadriceps, 1290
for muscle-tendon unit contusion and strains, 1281, 1281*b*
for muscle-tendon unit laceration, 1282, 1284
for neurologic patients, 117, 123*b*
objectives of, 105
for osteoarthritis, 123, 124*b*
for shoulder instability, 1168
for supraspinatus tendinopathy, 1287
therapeutic modalities of, 110–117, 111*f*
aquatic therapy as, 122–123
cryotherapy as, 110–111, 111*b*, 111*f*
extracorporeal shock wave therapy as, 115, 115*b*
joint mobilizations as, 115*t*, 116*b*
laser therapy as, 113*b*–114*b*, 113*f*
manual therapies as, 115–117
massage or soft tissue mobilization as, 115–116, 116*b*, 116*f*
neuromuscular electrical stimulation as, 114, 114*b*, 114*f*
passive range of motion and stretching as, 116–117, 117*b*, 117*f*
therapeutic exercise as, 117–121
therapeutic ultrasound as, 112–113, 112*f*, 113*b*
transcutaneous electrical nerve stimulation as, 114, 114*b*
Physical status, rating of, 26, 27*t*
Physical therapy. *see* Physical rehabilitation.
Physio ball, as neurologic rehabilitation exercises, 121, 121*f*
Physiologic saline solution, for hyperkalemia, 828*b*
Physiotherapy. *see* Physical rehabilitation.
Phytochemicals, for cognitive dysfunction syndrome, 1445–1447
Pigment gallstones, 578
Pilonidal sinus, 249–250
cervical, 249, 249*f*
classification of, 249, 249*t*
defined, 249
differential diagnosis of, 250
imaging of, 249, 250*f*
nasal, 249, 250*f*
treatment of, 250
Pimobendan (Vetmedin)
for cardiac disease, 789*b*
for congestive heart failure, 809*b*
Pin fixation. *see also* Intramedullary (IM) pins.
in thoracolumbar spinal trauma, 1424*f*
Pink tetralogy, 815

Pinna
neoplasia of, 324–327
diagnosis of, 324–325
clinical presentation in, 324–325
imaging in, 325, 326*f*
laboratory findings in, 325
physical examination findings in, 325, 326*f*
differential diagnosis of, 325
general considerations and clinically relevant pathophysiology, 324, 326*f*
medical management of, 325–327
postoperative care and assessment for, 327
prognosis for, 327
surgical technique for, 327, 327*b*
surgical treatment for, 327
anesthesia for, 327
positioning for, 327
preoperative management of, 327
surgical anatomy for, 327
suture materials and special instruments for, 327
squamous cell carcinoma of, 324, 326*f*
surgical anatomy of, in canine, 305, 306*f*
traumatic lesions of, 323–324, 324*f*
Piperacillin, 80
Piperacillin/tazobactam (Zosyn), 81*t*
Piprants, 150–151
Piroxicam (Feldene), for canine cystic transitional cell carcinoma, 710*b*
Pit vipers, 244
Pitting, of instruments, 55, 57*t*
Pituitary adenoma, 597–599
complications of, 599
definitions for, 597
diagnosis of, 597–598, 597*b*, 598*f*
history in, 597, 597*b*
imaging in, 598, 598*f*
laboratory findings in, 598
physical examination in, 597–598
differential diagnosis of, 598
general considerations and clinically relevant pathophysiology, 597
macroadenoma as, 597, 598*f*
microadenoma as, 597
prognosis for, 599
surgical treatment of, 598–599
anatomy for, 599, 599*f*
anesthesia for, 599
postoperative care and assessment after, 599, 599*b*
preoperative management of, 599
suture materials and special instruments for, 599
technique for, 599
Pituitary gland
healing of, 589
surgery of, 586–599
Pituitary neoplasia, 597–599
complications of, 599
definitions for, 597
diagnosis of, 597–598, 597*b*, 598*f*
history in, 597, 597*b*
imaging in, 598, 598*f*
laboratory findings in, 598
physical examination in, 597–598
Pituitary neoplasia *(Continued)*
differential diagnosis of, 598
general considerations and clinically relevant pathophysiology, 597
macroadenoma as, 597, 598*f*
microadenoma as, 597
prognosis for, 599
surgical treatment of, 598–599
anatomy for, 599, 599*f*
anesthesia for, 599
postoperative care and assessment after, 599, 599*b*
preoperative management of, 599
suture materials and special instruments for, 599
technique for, 599
Pituitary tumors, 597
functional, 597
Pituitary-dependent hyperadrenocorticism (PDH), 586
Pivot shift, 1227
Pixels, 170
Planking, on blocks and balls, as therapeutic exercise, 119
Plantigrade stance, 1084
Plasma
fresh-frozen, 31, 32*t*
for disseminated intravascular coagulation, 594, 594*b*, 638*b*
platelet-rich. *see* Platelet-rich plasma.
Plasma sterilization, 6*t*, 7–9
tape and indicator strips for, 11*f*
Plasma transudates, in wound healing, 179–180
Plasmatic inhibition, 233–234
Plastic and reconstructive surgery
flaps in
advancement, 218
axial pattern, 222–226, 223*f*
composite (compound), 226–231
interpolation, 218
microvascular transfer, 232–237
muscle, 228–231
omental, 231–232, 233*f*
pedicle, 217–232
tubed in, 221–222, 222*f*
pouch and hinge, 218–221, 221*f*
rotational, 218
transposition, 218
for irregular skin defects, 214–217
principles of, 204–237
skin stretching and expansion as, 207–208, 209*f*
skin tension and elasticity as, 204–217
suture patterns as, 208–210
tension lines and tension relief as, 204–208
skin grafts in, 232–237
Plastic pouches, for surgical pack wrapping, 12*t*
Plasticity, of suture, 61*b*
Plate(s), bone. *see* Bone plates; Plate and screw fixation.
Plate and screw fixation, 1016–1023
application of, 1019–1021, 1021*f*
for bridging plate, 1022, 1022*f*
for buttress plate, 1022
Plate and screw fixation *(Continued)*
for compression plate, 1021–1022, 1021*b*–1022*b*, 1021*f*
lag screw in, 1019–1020, 1020*b*, 1020*f*
for locking plate, 1022–1023, 1023*b*
locking screw in, 1021
for neutralization plate, 1022
plate screw in, 1021, 1021*f*
position screw in, 1020–1021
equipment and supplies for, 1017–1019
plates as, 1018–1019, 1018*f*–1019*f*
screws as, 1017–1018, 1017*f*
indications and biomechanical principle of, 1016–1017
postoperative care for, 1023
Platelet(s), in wound healing, 179–180
Platelet-derived growth factor (PDGF), 971
Platelet-rich fibrin, 968–970
Platelet-rich plasma (PRP), 971–973
applications of, 32*t*
for bone grafting, 995
concentrating system, 972*t*
defined, 968–970
formation of, 33, 971–972, 972*f*
for wound healing, 188
Platysma muscle, 1045*f*
Platysma myocutaneous flap, 226
Play bow, as therapeutic exercise, 121
Pleocytosis
eosinophilic, 1322
mononuclear cell, 1322
neutrophilic, 1322
Pleurae
defined, 916
healing of, 924–925, 926*f*
parietal, 916
surgical anatomy of, 918–920
visceral, 916, 937
Pleural cavity, 916, 918–920
Pleural cavity surgery, 916–955
anesthetic considerations for, 918, 918*b*, 919*t*–920*t*
antibiotics for, 918
for chylothorax, 941–947
complications of, 926
definitions for, 916
healing after, 924–925, 926*f*
for mediastinal cysts, 951–954
for peritoneopericardial diaphragmatic hernia, 931–933
for pleural effusion, 937–941
for pneumothorax, 933–937
postoperative care and assessment for, 925
preoperative concerns in, 916–918, 916*b*–917*b*, 917*t*
for pyothorax, 947–951
special age considerations to, 926
surgical anatomy for, 918–920
surgical techniques of, 920–924
continuous thoracic suction for, 924, 925*f*–926*f*
needle thoracentesis for, 920–922, 921*f*
thoracostomy tube placement for, 922–924
thoracostomy tube removal for, 924
suture materials and special instruments for, 925

Pleural cavity surgery *(Continued)*
for thymic branchial cysts, 951–954
for thymomas, 951–954
for traumatic diaphragmatic hernia, 926–931
Pleural effusion, 937–941
clinical presentation of, 937
definitions for, 916, 937
diagnosis of, 937–938
diagnostic imaging of, 938, 938*b*, 938*f*
differential diagnosis of, 938
general considerations and clinically relevant pathophysiology, 937
laboratory findings in, 938
medical management of, 938
nocardial, 948*f*
physical examination findings in, 937–938
prognosis of, 941
surgical treatment of, 939
anesthesia for, 939, 939*t*–940*t*
postoperative care and assessment for, 939
preoperative management of, 939
surgical anatomy for, 939
surgical technique for, 939
vascular access port and Jackson-Pratt drain for, 922–923, 922*f*
Pleuritis, fibrosing, 924–925, 926*f*
Pleurodesis
definition for, 916
mechanical, 936
Pleuroperitoneal shunting, for chylothorax, 946–947, 946*b*, 946*f*
Pleurovenous shunting, for chylothorax, 946–947, 946*b*, 946*f*
Pliability, of suture, 61*b*
Plication, intestinal
definition for, 433
due to foreign body, 416–417, 417*f*
to prevent recurrence of intussusception, 448, 448*b*, 448*f*
PLR (pupillary light reflex), 1324–1325
Plug grafts, 235
PMMA. *see* Polymethylmethacrylate.
Pneumocystogram, of ectopic ureter, 665
Pneumomediastinum, 934–935, 934*f*
Pneumonectomy, definition for, 884
Pneumonia, aspiration, treatment of, 343, 343*b*, 367, 367*b*
Pneumothorax, 933–937
clinical presentation of, 935
closed, 933
definitions for, 916, 933
diagnosis of, 935–936
diagnostic imaging of, 936, 936*b*, 936*f*
differential diagnosis of, 936
general considerations and clinically relevant pathophysiology, 933–935, 935*b*
idiopathic, 933
laboratory findings in, 936
medical management of, 936
open, 933
physical examination findings in, 935, 935*b*
postoperative care and assessment for, 937
Pneumothorax *(Continued)*
prognosis of, 937
spontaneous
defined, 933
pathophysiology of, 934*f*, 935
secondary, 935
surgical technique for, 937, 937*b*
surgical treatment of, 936–937
suture materials and special instruments for, 937
tension, 933
traumatic, 933–934
PNS (peripheral nervous system) disorders. *see* Peripheral nervous system (PNS) disorders.
pO_2 (transcutaneous oxygen) monitoring, to assess skin viability, 189–190
Pocket procedure, for third eyelid gland prolapse (cherry eye), 285–286, 286*f*
Pododermatitis, 250
treatment of, 250
Podoplasty, fusion, 265
Poliglecaprone 25 (Monocryl) sutures, 61*b*, 62
Polyamide (Nylon, Ethilon, Nurolon, Dermalon, Surgilon) sutures, 62, 63*t*
Polyarthritis, 1134
defined, 1134
feline chronic progressive, 1153–1154
definition for, 1153
diagnosis of, 1135–1137, 1154*f*
differential diagnosis of, 1154
general considerations and clinically relevant pathophysiology, 1153
medical management of, 1154, 1154*b*
prognosis of, 1154
surgical treatment for, 1154
lyme arthropathy as, 1149–1151, 1150*b*
nonerosive idiopathic immune-mediated as, 1151–1152, 1151*b*
rickettsial and anaplasmal, 1149
Polybutester (Novafil) sutures, 62, 63*t*
Polydioxanone (PDS II) sutures, 62, 63*t*
Polyester (Mersilene) surgical mesh, 68
Polyester (Mersilene, Ethibond, Dacron, Ti•cron) sutures, 62, 63*t*
Polyethylene glycol (PEG), for cervical spine surgery, 1366
Polyethylene glycol (PEG) electrolyte solution (Colyte, GoLytely), for large intestinal and rectal surgery, 467, 467*b*
Polyglactin 910 (Vicryl) surgical mesh, 68
Polyglactin 910 (Vicryl) sutures, 62, 63*t*
Polyglycolic acid (Dexon) surgical mesh, 68
Polyglycolic acid (Dexon) sutures, 62, 63*t*
Polyglyconate (Maxon) sutures, 62, 63*t*
Polyglytone 6211 (Caprosyn) sutures, 62, 63*t*
Polyhexamethylene biguanide (Kerlix) dressings, 197*t*–198*t*, 199–200
for outer layer of bandage, 201
Polyionic isotonic fluids, 31
Polymer(s), for bone grafting, 995
Polymeric diets, 93*t*
Polymerized caprolactam (Supramid, Braunamid, Vetcassette II) sutures, 63*t*
Polymethylmethacrylate (PMMA)
for craniocervical junction anomalies, 1392, 1393*f*
for hemivertebra, 1418, 1419*f*
for lumbosacral trauma, 1440–1441, 1441*f*–1442*f*
for spinal trauma, 1402, 1402*f*
for thoracolumbar spinal trauma, 1424*f*
Polymethylmethacrylate (PMMA) plug, for cervical spondylomyelopathy, 1384–1385, 1385*f*
Polymyositis, autoimmune, 1462–1463
Polyp(s)
definition for, 475
gastric, 425
endoscopic removal of, 160, 427
inflammatory, 327–330
multiple. *see* Chronic antral mucosal hypertrophy.
Polypropylene fabric, for surgical pack wrapping, 12*t*
Polypropylene mesh, 68
Polypropylene (Prolene, Surgilene, Fluorofil) sutures, 62, 63*t*
Polyradiculoneuritis, acute idiopathic, 1463–1464
Polysulfated glycosaminoglycans, for joint disease, 1139
Polytetrafluoroethylene (Teflon) injection, for urinary incontinence, 714
Polyurethane film dressings (Tegaderm, OpSite, Bioguard, Bioclusive), 196, 197*t*–198*t*
Polyurethane foam dressings (Copa, Permafoam), 197*t*–198*t*, 199
Polyvinylidene spinal plate, for cervical spondylomyelopathy, 1385, 1387*f*
Pons, 1324*f*
Poor prognosis, 27, 29*t*
Popliteal lymph nodes, 631, 632*f*
Popliteus muscle, 1234*f*
Porcine bladder extracellular matrix dressing (ACell Vet, Scaffold), 197*t*–198*t*
Porcine small intestinal submucosa (Vet BioSISt), 68
Porcine small intestinal submucosa (SIS) dressing, 197*t*–198*t*, 200
Portal, for arthroscopy, 158
Portal pressure, normal, 558, 558*b*
Portal system, 556, 557*f*
Portal vein, 543, 543*f*, 556, 558*f*
Portal vein hypoplasia (PVH)
defined, 550–551
general considerations and clinically relevant pathophysiology, 551
history of, 552, 552*b*
physical examination findings in, 552
prognosis for, 563
Portoazygos connections, 557, 558*f*
Portography
jejunal, 559, 559*f*
mesenteric, 556, 556*f*
retrograde, 556
transvenous retrograde, 559–560, 560*b*, 560*f*

Portosystemic shunts (PSSs), 550–563
acquired, 550–551
ameroid constrictors for, 555–556, 555*f*
congenital, 550
CT of, 174–175, 174*f*
definitions for, 550
diagnosis of, 551–554, 551*b*
clinical presentation in, 551–552
history of, 552, 552*b*
imaging in, 552–553, 552*b*, 552*f*–553*f*
physical examination findings in, 552
signalment for, 551–552
differential diagnosis of, 554
general considerations and clinically relevant pathophysiology, 550–551, 550*f*–551*f*
medical management of, 554–555, 555*b*
multiple, 550–551, 551*f*
portography of
jejunal, 559, 559*f*
mesenteric, 556, 556*f*
retrograde, 556
transvenous retrograde, 559–560, 560*b*, 560*f*
prognosis for, 563
surgical treatment of, 555–556
anatomy for, 556, 556*b*, 557*f*
anesthesia for, 556
positioning for, 556
postoperative care and assessment after, 562–563
preoperative management of, 556
suture materials and special instruments for, 562, 562*b*
techniques for, 556–562, 557*b*, 558*f*
Portosystemic vascular anomalies. *see* Portosystemic shunts.
Position screws, 1017
application of, 1020–1021
Positioning, preoperative, 37
Positive contrast celiography, 927
Positive sharp waves, in electromyography, 1317–1318, 1317*f*, 1317*t*
Positron emission tomography (PET), physics of, 170–171, 171*f*
Positron emission tomography/computed tomography (PET/CT), physics of, 171
Postmyelographic seizures, 1313
Postoperative bandages, 202
Postoperative recovery area
daily cleaning of, 25
description and function of, 23
Postural reactions, 1332–1334
ascending proprioceptive pathways in, 1332–1333, 1333*f*
conscious *vs.* unconscious proprioception and, 1332–1333
hemiwalking in, 1332, 1334*f*
hopping in, 1333–1334, 1333*f*
proprioceptive positioning for, 1333–1334, 1333*f*
tactile placing in, 1333–1334, 1333*f*
wheelbarrowing in, 1333–1334, 1334*f*
Posture, 1328–1331
decerebellate rigidity in, 1330–1331
decerebrate rigidity in, 1330–1331, 1331*f*
defined, 1328–1330
head tilt in, 1328–1330, 1330*f*
Posture *(Continued)*
head turn in, 1328–1330, 1330*f*
Schiff-Sherrington, 1330, 1331*f*
wide-based stance in, 1330, 1330*f*
Potassium
high, 28*t*
low, 28*t*
Potassium bromide, for brain surgery, 1339*t*
Potassium gluconate, for hyperaldosteronism, 593
Potassium supplementation
of crystalloid solutions, 31, 32*t*
for peritonitis, 530–531, 530*t*
Potts scissors, 796–797, 796*f*
Pouch flaps, 218–221, 221*f*
Povidone-iodine (PVI)
for sterile skin preparation, 38, 38*t*, 39*f*
for surgical scrub, 46*t*
as wound cleansers, 184*t*, 188–189
Power instruments, for arthroscopy, 167
PPA (phenylpropanolamine)
for urinary incontinence, 713, 714*b*
for urinary sphincter leakage, 666*b*
PPDH. *see* Peritoneopericardial diaphragmatic hernia.
PPN (partial parenteral nutrition), defined, 90
Pradofloxacin (Veraflox), 81*t*, 82
Prednisolone
for adrenocortical insufficiency, 587*b*
after adrenalectomy, 587*b*
after hypophysectomy, 599*b*
for autoimmune polymyositis, 1463
for brain tumors, 1359–1360, 1360*b*
for cervical spine surgery, 1366
for Chiari-like malformation, 1356
for congenital hydrocephalus, 1349, 1349*t*
for feline chronic progressive polyarthritis, 1154*b*
for immune-mediated polyarthritis, 1151*b*
for insulinomas, 610*b*
for noninfectious inflammatory disease, 1455*b*
for perianal fistula, 502, 503*b*
for rheumatoid arthritis, 1153*b*
for steroid-responsive meningitis-arteritis, 1456
for tracheal collapse, 871*b*
Pregabalin, 148*t*–149*t*
for brain surgery, 1339–1340, 1339*t*
for cervical disc disease, 1378–1379
for cervical spine surgery, 1366
for Chiari-like malformation, 1356
for cognitive dysfunction syndrome, 1445–1447
Pregnancy, methods to determine, 721–722, 721*t*
Pregnancy prevention, options for, 728–729, 729*b*
Pregnancy risk, methods to determine, 720–721, 721*t*
Pregnancy termination, 728–729, 729*b*
Premedication, 125
benzodiazepines for, 127*t*–131*t*, 131
diazepam as, 127*t*–131*t*, 131
flumazenil as, 127*t*–131*t*, 131
midazolam as, 127*t*–131*t*, 131
zolazepam as, 127*t*–131*t*, 131
Premedication *(Continued)*
for induction
etomidate as, 127*t*–131*t*, 134
ketamine as, 127*t*–131*t*, 134–135
propofol 28 as, 127*t*–131*t*, 134
propofol as, 127*t*–131*t*, 133–134
thiopental as, 127*t*–131*t*, 133
opioids for, 127*t*–131*t*, 132–133, 133*b*
buprenorphine as, 133
butorphanol as, 127*t*–131*t*, 133
fentanyl as, 127*t*–131*t*, 133
hydromorphone as, 127*t*–131*t*, 133
meperidine as, 127*t*–131*t*, 133
methadone as, 127*t*–131*t*, 133
morphine as, 127*t*–131*t*, 133
nalbuphine as, 127*t*–131*t*, 133
oxymorphone as, 127*t*–131*t*, 133
remifentanil as, 127*t*–131*t*, 133
tramadol as, 127*t*–131*t*, 133
Premolars, 1037*f*
Preoperative and intraoperative care, of surgical patient, 26–35
for acid-base abnormalities, 27
client communication in, 27
determination of surgical risk in, 27, 29*t*
fluid therapy for, 31–34, 32*t*
blood products for, 33–34, 34*b*
colloid solutions for, 32–33, 33*b*
crystalloid solutions for, 31–32, 32*t*
history taking in, 26
laboratory data in, 26, 26*b*, 28*t*
for nutritional status, 27–28
oxygen therapy in, 29–31, 29*b*
face mask delivery of, 29–30, 30*t*
flow-by, 29, 30*f*, 30*t*
methods for, 30*t*
tent or Elizabethan collar canopy for, 30*t*
via nasal catheters, 30–31, 30*t*, 31*b*, 31*f*
via oxygen cage, 30*t*, 31
patient stabilization in, 27–29
physical examination in, 26, 27*t*
surgical safety checklist in, 34, 35*f*
for trauma, 28–29, 29*b*, 29*f*
Preoperative preparation, 36–41
clamping of prepuce in, 39, 39*f*
dietary restrictions in, 36
draping in, 39–40
for abdominal incision, 39, 39*f*
cutting fenestration in, 40*f*
for limb, 40, 40*f*
sterile Backhaus towel clamps in, 39–40, 39*f*
"toweling-in" (additional draping after skin incision) in, 40
exclusion of paw from surgical area in, 37, 37*f*
excretions in, 36
flushing of prepuce in, 37, 37*f*
general cleansing scrub in, 37
hair removal in, 36–37, 37*f*
ophthalmic antibiotic ointments or lubricants in, 37
positioning for, 37
sterile skin preparation in, 38–39, 38*b*
alcohol-based solutions as, 38–39, 38*t*, 39*b*
characteristics of ideal, 38, 38*b*

Preoperative preparation *(Continued)*
chlorhexidine as, 38, 38*t*
povidone-iodine as, 38, 38*t*, 39*f*
prevention of pooling of alcohol with, 39*b*
properties of, 38, 38*t*
Prepubic catheterization, 678, 685–686, 687*f*
Prepubic musculature, 520, 520*f*
Prepubic tendon, 520
Prepubic urethrostomy, 692, 694*f*
Prepuce
anatomy of, 727
clamping of, 39, 39*f*
flushing of, 37, 37*f*
physical examination of, 722
Prepuce reconstruction, for hypospadias, 776, 777*f*
Preputial lacerations, 786
Preputial lengthening, for paraphimosis, 782, 782*f*
Preputial trauma and neoplasia, 785–786
complications of, 786
definitions for, 785
diagnosis of, 785–786
differential diagnosis of, 786
general considerations and clinically relevant pathophysiology, 785, 785*b*, 785*f*
medical management of, 786
prognosis for, 786
surgical treatment of, 786
Preputiotomy, 781–782
Presbycusis, definition for, 302
Prescrotal castration
closed, 734
open, 732–733, 733*f*
Prescrotal urethrostomy, 688–689, 691*f*
Prescrotal urethrotomy, 687–688, 690*f*
Pressure autoregulation, 1338
Pressure bandages, 202
Pressure relief bandages, 202–203, 202*f*
Pressure sores, 246–247
classification of, 246, 246*t*
common sites of, 246, 247*b*
complications of, 246
prevention of, 246–247, 247*b*
treatment of, 246–247, 246*t*, 247*b*
Presterilization wraps, 12
Presuturing, for skin stretching and expansion, 207–208, 209*f*
Pretragic incisure, 305, 306*f*
Prevacuum sterilizer, 4
Priapism, 779
Prilosec. *see* Omeprazole.
Primary joint neoplasms, 1308
Primary layer, of wound dressing, 195–200
factors in selection of, 195, 195*b*
hydrophilic, 195–196, 195*b*
selection of
based on purpose, 195, 196*t*
based on wound characteristics, 195, 197*t*
types of, 195, 197*t*–198*t*
wound contraction and, 195, 195*b*
Primary palate, 342
Primary secretory otitis media (PSOM), 316
Primary stifle restraints, 1252
Primary wound closure, 193
delayed, 193
Primary wound healing, 193
Principen. *see* Ampicillin.
Prinivil (lisinopril), for cardiac disease, 789*b*
Pro-Banthine (propantheline bromide) , for bradycardia, 828*b*
Procainamide (Pronestyl)
for cardiac disease, 789*b*
for gastric dilatation-volvulus, 423–424, 425*b*
Procalcitonin (PCT), in peritonitis, 528–529
Procarbazine, for noninfectious inflammatory disease, 1455*b*
Proctoscopy, 158, 159*b*
for intestinal neoplasia, 476
Procurvatum, 958*b*
Proestrus
hormone concentrations during, 720–721
physical examination during, 720
Progesterone, in females, 720–721
Progestins, for benign prostatic hyperplasia, 763–764, 764*t*
Proglycem (diazoxide), for insulinoma, 610, 610*b*
Projection, 170
Prolapse
uterine, 760*f*, 761–762
vaginal, 759–761
Prolene (polypropylene) sutures, 62, 63*t*
Proliferative phase, in healing of small intestine, 449
PROM (passive range of motion), 116–117, 117*b*, 117*f*
Promontory, 305
Pronator teres muscle, 1066*f*, 1069*f*
transection of, exposure of medial coronoid process, 1180, 1181*f*
Pronestyl (procainamide)
for cardiac disease, 789*b*
for gastric dilatation-volvulus, 423–424, 425*b*
Propantheline bromide (Pro-Banthine), for bradycardia, 828*b*
Proper hepatic arteries, 543, 543*f*
Prophylactic antibiotic therapy, 86–88
considerations for selection and administration of, 87*b*
defined, 79
most likely organisms and, 87, 87*t*
perioperative, 86
postoperatively, 88
route of administration of, 87–88
selection and timing of, 87
surgical procedures that warrant, 86, 86*b*
Prophylactic gastropexy
laparoscopic-assisted, 410, 413*f*
mini-laparotomy, 414–415, 415*f*
Propofol
for brain surgery, 1340
for extrahepatic biliary surgery, 583*b*
for induction, 127*t*–131*t*, 133–134
for liver surgery, 540–542, 541*t*–542*t*
with peritonitis, 533–534
Propranolol (Inderal)
for cardiac disease, 789*b*
for feline hyperthyroidism, 620–621, 620*b*
for pheochromocytoma, 594–596
Proprioception
conscious *vs.* unconscious, 1332–1333
general, 1332–1333
Proprioceptive deficits
definition for, 957
due to cauda equina lesions, 1427
Proprioceptive neuromuscular facilitation (PNF), 105, 117, 117*b*
Proprioceptive pathways, ascending, 1332–1333, 1333*f*
Proprioceptive positioning, 1333–1334, 1333*f*
Proptosis
definition for, 291
traumatic, 294–296
Propulsid (cisapride), to improve urination, 701*t*
Propylthiouracil (PTU), for feline hyperthyroidism, 619–620
Proscar (finasteride), for benign prostatic enlargement, 764*t*
Prostaglandin $F_{2\alpha}$ ($PGF_{2\alpha}$, Lutalyse)
for pregnancy prevention or termination, 729*b*
for pyometra, 757*b*
Prostate gland, 726–727, 727*b*
biopsy of, 742
innervation to, 727*f*
normal defense mechanisms against infection of, 764–765, 765*b*
Prostatectomy, 742–743
complications of, 745, 745*b*
defined, 720
subtotal, 742–743
with capsulectomy, 743, 744*f*
intracapsular, 743, 744*f*
total, 742, 743*f*
Prostatic abscess, 764–768
complications of, 767, 767*b*
definitions for, 764
diagnosis of, 765–766
history in, 765, 765*b*
imaging in, 765, 765*b*
laboratory findings in, 765–766, 766*b*
physical examination findings in, 765, 765*b*
signalment in, 765
differential diagnosis of, 763*t*, 766
general considerations and clinically relevant pathophysiology, 764–765, 765*b*
medical management of, 766, 766*f*
prognosis for, 767–768
surgical treatment of, 766–767
anatomy in, 766
anesthesia for, 766
positioning for, 766–767
postoperative care and assessment of, 767
preoperative management of, 766
surgical technique for, 767, 767*f*
Prostatic arteries, 689*f*, 726–727

Prostatic biopsy, 742
  complications of, 745*b*
  open, 742
  palpation-guided, 742
  transrectal fine-needle aspiration in, 742
  ultrasound-guided, 742
Prostatic carcinomas, 771
Prostatic cysts, 763*t*, 768–771
  definitions for, 768
  diagnosis of, 768–769, 768*f*, 769*b*
  differential diagnosis of, 769
  general considerations and clinically relevant pathophysiology, 768, 768*f*
  medical management of, 769
  paraprostatic (periprostatic), 768, 769*f*
  parenchymal, 768
  prognosis for, 771
  surgical treatment of, 769
    anesthesia for, 769
    positioning for, 769
    postoperative care and assessment of, 771
    preoperative management of, 769
    surgical technique for, 769–771, 769*f*
      marsupialization as, 769–771, 770*f*
      omentalization as, 769, 770*f*
Prostatic drainage, ultrasound-guided percutaneous, 766, 766*f*
  complications after, 767, 767*b*
Prostatic fluid, cytology of, 722
Prostatic hemangiosarcoma, 771
Prostatic hyperplasia, 762–764
  definitions for, 762
  diagnosis of, 762–763, 763*b*
  differential diagnosis of, 763, 763*t*
  general considerations and clinically relevant pathophysiology, 762
  glandular or complex, 762
  key points in, 763*b*
  medical management of, 763–764, 764*t*
  prognosis for, 764
  surgical treatment of, 764
Prostatic leiomyosarcoma, 771
Prostatic neoplasia, 771–772
  definitions for, 771
  diagnosis of, 771–772
  differential diagnosis of, 763*t*, 772
  general considerations and clinically relevant pathophysiology, 771, 772*b*
  medical management of, 772
  prognosis for, 772
  surgical treatment of, 723*t*–724*t*, 772
Prostatic palpation, 722
Prostatitis, 764
Prosthetic capsule, for coxofemoral luxation, 1224, 1224*f*
Prosthetic ligament, for collateral ligament injury, 1206
Protein C, with portosystemic shunt, 554
Protein concentration, in cerebrospinal fluid, 1321, 1321*b*
Protein synthesis, inhibition by antibiotics of, 81–82, 81*b*–82*b*
Protein-calorie malnutrition (PCM), 90
  causes of, 90
  consequences of, 90
  diagnosis of, 90, 91*b*
Protein-losing enteropathy, 462
Protein-rich gel, 968–970
Proteoglycans, 1141
Proton density (PD) sequencing, 169
Proton pump inhibitors
  for benign gastric outflow obstruction, 426, 426*b*
  for gastrinomas, 613, 613*b*
Protonix. *see* Pantoprazole.
Proximal epiphysis, surgical approach to, 1062–1063, 1063*f*
Proximal femoral fracture
  diagnosis of, 1114–1115, 1115*b*
  differential diagnosis of, 1115
  general considerations and pathophysiology of, 1114, 1114*f*
  medical management of, 1115
  prognosis for, 1118, 1119*f*
  surgical treatment of, 1115
    anesthesia for, 1115
    complications in, 1118
    lag screw for, 1117, 1117*f*
    positioning for, 1115
    postoperative care and assessment after, 1118, 1118*f*
    preoperative management of, 1115
    surgical anatomy for, 1115
    surgical technique for, 1115–1118
    suture materials and special instruments for, 1118
    triangulated Kirschner wires for, 1116–1117, 1117*f*
Proximal femur, surgical approach to, 1115–1116, 1116*f*
Proximal humerus
  cancellous bone autografts from, 992, 992*f*
  osteochondritis dissecans
    arthroscopic treatment of, 1156–1158
      indications for, 1156
      instrumentation for, 1156, 1156*b*
      portal sites and technique for, 1156–1158, 1157*f*–1158*f*
      postoperative care and assessment for, 1158
    definitions for, 1154
    diagnosis of, 1155–1156, 1155*b*, 1156*f*
    differential diagnosis of, 1156
    general considerations and clinically relevant pathophysiology, 1154–1155, 1155*b*, 1155*f*
    medical management of, 1156
    open surgical techniques for, 1158*b*
      caudal approach for, 1159
      infraspinatus tenotomy for, 1158–1159
      postoperative care and assessment after, 1159
      surgical treatment of, 1156–1158
    prognosis of, 1159
    surgical treatment of, 1156–1158
Proximal interphalangeal joint, arthrodesis of, 1091*f*
Proximal intertarsal subluxation, 1267–1268, 1268*f*
Proximal radial fractures, stabilization of, 1075, 1075*f*
Proximal radial physis, approach to, 1078, 1078*f*
Proximal radius, approaches to, 1075
Proximal tibia
  cancellous bone autografts from, 992
  surgical approach to, 1129
Proximal tibial fractures, stabilization of, 1129–1130, 1130*f*
Proximal ulna, approaches to, 1075
Proximal ulnar fractures, stabilization of, 1075, 1075*f*
Proximal ulnar osteotomy, for medial compartment disease, 1185
Proximal ulnar segmental osteotomy, 1182, 1183*f*
Proximate Plus (skin staples), 67
PRP. *see* Platelet-rich plasma.
PS. *see* Pulmonic stenosis.
Pseudochylous effusion, 943
Pseudocysts, pancreatic, 606–609
  definitions for, 606–607
  diagnosis of, 607–608, 607*f*, 608*b*
  differential diagnosis of, 608
  general considerations and clinically relevant pathophysiology, 607, 607*b*, 607*f*
  medical management of, 608
  prognosis for, 609
  surgical treatment of, 608, 609*b*
Pseudomonas aeruginosa, otitis externa due to, 303–305
Pseudomonas spp., pyothorax due to, 948*t*
PSSs. *see* Portosystemic shunts.
Psychogenic dermatoses, 248–249, 248*f*
  treatment of, 249
Psyllium (Metamucil), after prostatic or perineal surgery, 744*b*
PTE (pulmonary thromboembolism)
  advanced imaging modalities for, 175
  after adrenalectomy, 586, 589
PTH (parathyroid hormone), 616
  serum, 625, 625*t*
PTU (propylthiouracil), for feline hyperthyroidism, 619–620
Pubic and ischial osteotomy, bilateral, 471
Pubic fractures, 1095
  definitions for, 1095
  diagnosis of, 1095, 1096*f*
  differential diagnosis of, 1096
  general considerations and pathophysiology of, 1095–1099, 1095*b*
  medical management of, 1096
  prognosis for, 1099
  surgical treatment of, 1096–1097, 1096*b*
    anesthesia for, 1096
    application of plates and screws in, 1096
    complications in, 1099
    positioning for, 1097
    postoperative care and assessment after, 1098–1099
    preoperative management of, 1096
    surgical anatomy for, 1096–1097, 1096*b*
    surgical technique for, 1097–1098, 1097*f*–1098*f*
    suture materials and special instruments for, 1098

Pubic symphysiodesis, juvenile, 1212, 1215, 1215*f*
Pudendal artery, internal, 727*f*
Pudendal nerve, 689*f*, 726–727, 727*f*
Pug/Maltese encephalitis, 1453
Pullout value of suture, 61*b*
Pulmonary abscesses, 903–905
  clinical presentation of, 904
  definition for, 903
  diagnosis of, 904
  diagnostic imaging of, 904, 904*f*
  differential diagnosis of, 904
  general considerations and clinically relevant pathophysiology, 903
  laboratory findings in, 904
  medical management of, 904
  physical examination findings in, 904
  postoperative care and assessment for, 905
  prognosis of, 905
  surgical technique for, 904–905
  surgical treatment of, 904
  suture materials and special instruments for, 905
Pulmonary arteries, 794*f*, 889
Pulmonary artery banding, for ventricular septal defect, 812, 812*f*
Pulmonary edema
  due to electrical injury, 241
  reexpansion, 887
Pulmonary lobectomy
  complete
    defined, 884
    for pulmonary neoplasia, 903
    surgical technique for, 894–895, 896*f*
  partial
    defined, 884
    for pulmonary neoplasia, 903
    surgical technique for, 894, 895*f*
  thoracoscopic, for pulmonary neoplasia, 903
Pulmonary metastatic disease
  advanced modalities for, 175, 176*f*
  imaging of, 1301*b*
Pulmonary neoplasia, 900–903
  clinical presentation of, 900–901
  definition for, 900
  diagnosis of, 900–902
  diagnostic imaging of, 901–902, 901*b*–902*b*, 901*f*–902*f*
  differential diagnosis of, 902, 902*b*
  general considerations and clinically relevant pathophysiology, 900
  laboratory findings in, 902
  medical management of, 902
  physical examination findings in, 901
  surgical treatment of, 902–903
    anesthesia for, 902
    complications with, 903
    partial or complete lobectomy for, 903
    positioning for, 903, 903*b*
    postoperative care and assessment for, 903
    preoperative management of, 902
    prognosis of, 903
    surgical anatomy for, 902
Pulmonary neoplasia *(Continued)*
    suture materials and special instruments for, 903
    thoracoscopic biopsy or partial lobectomy for, 903
    thoracoscopic lobectomy, 903
Pulmonary osteoarthropathy, 1297–1298, 1298*f*
Pulmonary pleura, 916
Pulmonary thromboembolism (PTE), 887–888
  advanced imaging modalities for, 175
  after adrenalectomy, 586, 589
  management of, 888*b*
Pulmonary vein, 794*f*
Pulmonic stenosis (PS), 805–807
  definitions for, 805
  diagnosis for, 806
  differential diagnosis of, 806
  general considerations and clinically relevant pathophysiology, 805–806
  interventional treatment for, 806
  medical management of, 806
  prognosis for, 807
  surgical treatment of, 806–807
  type A, 805
  type B, 805
Pulmonic valve dysplasia. *see* Pulmonic stenosis.
Pulsed electromagnetic field, of open wounds, 189
Pulsion diverticulum, 383
Punch grafts, 235
Puncture wound, 183
Pupillary constriction
  evaluation of, 1324–1325
  neuroanatomic pathways for, 1324–1325, 1326*f*
Pupillary light reflex (PLR), 1324–1325
PVH (portal vein hypoplasia)
  defined, 550
  general considerations and clinically relevant pathophysiology, 551
  history of, 552, 552*b*
  physical examination findings in, 552
  prognosis for, 563
PVI (povidone-iodine)
  for sterile skin preparation, 38, 38*t*, 39*f*
  for surgical scrub, 46*t*
  as wound cleansers, 184*t*, 188–189
Pyelolithotomy, 650, 657, 658*f*, 669
Pylorectomy, 398
  with gastroduodenostomy (Billroth I), 403, 403*b*, 404*f*
Pyloric gastropathy, chronic hypertrophic, 425
Pyloric mucosal hypertrophy. *see* Chronic antral mucosal hypertrophy.
Pyloric muscle hypertrophy, congenital. *see* Pyloric stenosis.
Pyloric stenosis, 425
Pyloromyotomy, 403–406, 405*b*
  definition for, 398
  Fredet-Ramstedt, 405, 406*f*
Pyloroplasty, 403–406, 405*b*
  definition for, 398
  Heineke-Mikulicz, 405, 406*f*
  Y-U, 405–406, 406*b*, 407*f*
Pyoderma, 586
  due to redundant skin folds, 251
  interdigital, 250
    treatment of, 250
Pyometra, 528*b*, 752–759
  concurrent abnormalities with, 755, 755*b*
  definitions for, 752
  diagnosis of, 755–756, 756*b*, 756*f*
  differential diagnosis of, 756, 756*f*–757*f*
  general considerations and clinically relevant pathophysiology, 752–755, 754*b*
  medical management of, 756–757, 757*b*
  prognosis for, 759
  stump, 752
  surgical treatment of, 757–758
    anatomy in, 758
    anesthesia for, 753*t*–754*t*, 758
    complications of, 758
    positioning for, 758
    postoperative care and assessment of, 758
    preoperative management of, 757–758, 757*b*–758*b*
    surgical technique for, 758, 758*b*, 758*f*
Pyothorax, 947–951
  bacteria commonly associated with, 948*t*
  clinical presentation of, 948
  definition for, 947
  diagnosis of, 948–949
  diagnostic imaging of, 949
  differential diagnosis of, 949
  general considerations and clinically relevant pathophysiology, 947–948
  laboratory findings in, 949, 949*f*
  medical management of, 949–950, 949*b*–950*b*
  physical examination findings in, 948–949
  prognosis of, 950–951
  surgical treatment of, 950
    anesthesia for, 950
    positioning for, 950
    postoperative care and assessment for, 950
    preoperative management of, 950
    surgical anatomy for, 950
    surgical technique for, 950
    suture materials and special instruments for, 950
Pyridostigmine bromide, for acquired myasthenia gravis, 953*b*
Pythiosis
  definition for, 430
  of small intestine, 462–464
    diagnosis of, 462–463
      clinical presentation in, 462
      imaging in, 462–463
      laboratory findings in, 463, 463*f*
      physical examination findings in, 462
    differential diagnosis of, 463
    general considerations and clinically relevant pathophysiology, 462
    medical management of, 463
    postoperative care and assessment for, 463–464
    prognosis for, 464

Pythiosis *(Continued)*
surgical technique for, 463, 463*f*
surgical treatment of, 463
anesthesia for, 463
positioning for, 463
preoperative management of, 463
surgical anatomy for, 463
suture materials and special instruments for, 463
of stomach, 431, 431*f*
Pythium insidiosum, 430

Q
Quadrate lobe, of liver, 543*f*
Quadriceps contracture, 1289–1291
definitions for, 1289
diagnosis of, 1290, 1290*f*
differential diagnosis of, 1290
general considerations and clinically relevant pathophysiology, 1289–1290
medical management of, 1290
physical rehabilitation for, 1290
postoperative care and assessment for, 1291
prognosis of, 1291
surgical treatment for, 1290–1291
Quadriceps extensor mechanism, 1257, 1257*f*
Quadriceps muscle-tendon unit, surgical anatomy of, 1290
Quadriceps tie-down. *see* Quadriceps contracture.
Quadrigeminal cyst. *see* Intracranial arachnoid cyst.
Quadriparesis, 1332
Quadriplegia, 1332
Quarter drapes, 39

R
Radial, ulnar, musculocutaneous, and median (RUMM) nerve blocks, 152–153
Radial artery, 1069*f*
Radial carpal fractures, 1084
stabilization of, 1086
surgical anatomy of, 1085–1086
Radial fractures
diaphyseal, 1066–1073
comminuted
large butterfly fragment, 1071, 1072*f*–1073*f*
with multiple fragments, 1071–1072
definitions for, 1066
diagnosis of, 1066–1067, 1067*b*
differential diagnosis of, 1067
general considerations and pathophysiology of, 1066
medical management of, 1068, 1068*b*
oblique
long, 1071, 1072*f*–1073*f*
short, 1071, 1072*f*
prognosis for, 1073
surgical treatment of, 1068–1069, 1068*b*, 1072
anesthesia for, 1069
bone plates and screws in, 1071, 1071*f*
Radial fractures *(Continued)*
casts in, 1069, 1069*b*, 1070*f*
complications of, 1073, 1073*b*
craniomedial approach for, 1069, 1069*f*
external skeletal fixators in, 1069–1071, 1070*b*, 1070*f*–1071*f*
intramedullary pins in, 1069, 1069*b*
for midshaft comminuted fractures with multiple fragments, 1071–1072
for midshaft long oblique fractures or comminuted fractures with large butterfly fragment, 1071, 1072*f*–1073*f*
for midshaft transverse or short oblique fractures, 1071, 1072*f*
positioning for, 1069
postoperative care and assessment after, 1072–1073
preoperative management of, 1068–1069
surgical anatomy for, 1069
suture materials and special instruments for, 1072
transverse, 1071, 1072*f*
metaphyseal and articular, 1074–1076
caudal approach to, 1075, 1075*f*
definitions for, 1074
diagnosis of, 1074
differential diagnosis of, 1074
distal
approaches to, 1075
stabilization of, 1075, 1076*b*, 1076*f*
general considerations and clinically relevant pathophysiology, 1074
medical management of, 1074
prognosis for, 1076
proximal
approaches to, 1075
stabilization of, 1075, 1075*f*
surgical treatment of, 1074–1075, 1074*b*
anesthesia for, 1074
complications of, 1076
positioning for, 1075
postoperative care and assessment after, 1076
preoperative management of, 1074
surgical anatomy for, 1074–1075
suture materials and special instruments for, 1076
physeal, 1077–1079
definitions for, 1077
diagnosis of, 1077, 1077*b*
differential diagnosis of, 1077
general considerations and pathophysiology of, 1077
medical management of, 1077
prognosis for, 1079
surgical approach to
distal, 1078
proximal, 1078, 1078*f*
surgical treatment of, 1077–1078, 1077*b*
anesthesia for, 1078
complications of, 1079, 1079*f*
Radial fractures *(Continued)*
crossed Kirschner wires or Steinmann pins for stabilization of displaced fractures in, 1078, 1079*f*
positioning for, 1078
postoperative care and assessment after, 1078–1079
preoperative management of, 1077–1078
stabilization of nondisplaced fractures in, 1078
surgical anatomy for, 1078
suture materials and special instrument for, 1078
Radial growth deformities, 1079–1084
definitions for, 1079
diagnosis of, 1080, 1080*b*
differential diagnosis of, 1080
general considerations and pathophysiology, 1080
medical management of, 1080
prognosis for, 1084
surgical treatment of, 1080–1081, 1081*b*
anesthesia for, 1081
circular external fixator for, 1006–1007, 1007*b*, 1007*f*
complications of, 1084
oblique osteotomy for, 1082–1083, 1083*f*
ostectomy and free autogenous fat graft for, 1082, 1082*f*
partial physeal resection for, 1082, 1082*f*
positioning for, 1081
postoperative care and assessment after, 1083, 1083*b*
preoperative management of, 1081
preoperative planning for, 1081
surgical anatomy for, 1081
suture materials and special instruments for, 1083
Radial head, approach to, 1078*f*
Radial lengthening osteotomy, 1199
Radial nerve, 1055*f*
Radial ostectomy, free autogenous fat grafts and, 1082, 1082*f*
Radial osteotomy, oblique, 1082–1083, 1083*f*
Radial tears, 1243–1244
Radial-ulnar incongruence, 1174*t*, 1180–1183
complications of, 1183
definition for, 1180
diagnosis of, 1181–1182
differential diagnosis of, 1182
general considerations and clinically relevant pathophysiology, 1181
medical management of, 1182
prognosis of, 1183
surgical treatment of, 1182–1183, 1183*f*
Radiation, megavoltage, for brain tumors, 1359–1360, 1360*b*
Radiation therapy (RT)
of nasal tumors, 877
for pituitary neoplasia, 598
skin reactions to, 242–243, 243*b*
causes of, 242, 242*f*

Radiation therapy (RT) *(Continued)*
classification of, 242–243
early (acute), 242–243
late (chronic), 242–243
treatment of, 243
Radicular vessels, 1428
Radiculopathy, 1375
Radiofrequency (RF), for arthroscopy, 167
Radiosurgery
for hemostasis, 77–78
for pituitary neoplasia, 598
Radiotherapy. *see* Radiation therapy.
Radius
craniomedial approach for, 1069, 1069*f*
palpation of, 963
Radius curvus. *see* Radial growth deformities.
Rake retractors, 54
Range of motion (PROM)
defined, 116
passive, 116–117, 117*b*, 117*f*
Ranula
definition for, 331, 358
marsupialization of, 362, 363*f*
Rattlesnake, 244
Rayon/polyethylene glycol dressing (Telfa Pads, Dermacea), 197*t*–198*t*
RBCs (red blood cells)
high, 28*t*
packed, 32*t*
Rear limb, fracture disease of. *see* Quadriceps contracture.
Reconstruction plates, 1019
Reconstructive surgery. *see* Plastic and reconstructive surgery.
Recovery area
daily cleaning of, 25
description and function of, 23
Rectal artery
cranial, 484
middle, 484
Rectal polyps, endoscopic removal of, 160
Rectal prolapse, 504–507
complications of, 507
definition for, 504
diagnosis of, 505
clinical presentation in, 505
imaging in, 505
laboratory findings in, 505
physical examination findings in, 505, 505*f*
differential diagnosis of, 505, 505*b*
general considerations and clinically relevant pathophysiology, 504–505, 505*b*
medical management of, 505, 506*f*
postoperative care and assessment for, 506
prognosis for, 507
surgical technique for, 506, 506*f*
surgical treatment of, 505–506, 505*b*
anesthesia for, 505
positioning for, 505–506
preoperative management of, 505
surgical anatomy for, 505
Rectal pull-through, 482, 485–486, 486*b*, 486*f*
Rectal resection, 482, 484–487
anal approach to, 485, 485*f*
dorsal approach to, 486–487, 487*f*
lateral approach to, 487, 488*f*
rectal pull-through approach to, 485–486, 486*b*, 486*f*
ventral approach to, 484–485, 484*f*
Rectangular skin defects, 215, 216*f*
Rectum, 482–510
anesthetic considerations for, 483
antibiotics for, 483
complications of, 489, 489*b*
definitions for, 482
fecal incontinence of, 507–510
healing of, 487–488
postoperative care and assessment for, 488–489
preoperative concerns for, 482–483, 482*b*
prolapse of, 504–507
special age considerations for, 489
surgical anatomy of, 483–484, 484*b*
surgical techniques for, 484–487
anal sacculectomy, 487, 487*b*
rectal resection, 484–487
suture materials and special instruments for, 488
Rectus abdominis muscle, 513*f*, 520, 520*f*
Rectus fascia, sutures for, 65
Rectus femoris muscle, 1257*f*, 1290
Rectus sheath, 513*f*
Recurrent laryngeal nerve, 616*f*, 839
Recurvatum, 958*b*, 1032, 1033*f*
Red blood cells (RBCs)
in cerebrospinal fluid, 1321*b*, 1322
high, 28*t*
packed, 32*t*, 33
Red nucleus, 1331, 1332*f*
"Red out," in arthroscopy, 158
Reducible fractures, 985
Reduction, 958*b*
angle of, 1209, 1210*f*
Redundant skin folds, 251–253
of lips, 251
antidrool cheiloplasty in, 251, 253*f*
lip fold resection (cheiloplasty) in, 251, 252*f*
of nasal, 251–252, 253*f*
of tail, 252–253, 254*f*
of vulvar, 252, 254*f*
Reexpansion pulmonary edema, 887
Referred pain, 143–144
Reflex(es), spinal, 1334–1336
biceps, 1334–1335, 1335*f*
crossed extensor, 1336
cutaneous trunci (panniculus), 1336, 1336*f*
gastrocnemius, 1335*f*
patellar, 1335–1336, 1335*f*
pelvic limb withdrawal, 1335–1336
perineal (anal), 1336, 1336*f*
tendon (stretch), 1334
triceps, 1334–1335, 1335*f*
withdrawal, 1334
Regenerative medicine, 957–975
definitions for, 968–970, 968*b*
mechanism of action of, 973–974
platelet-rich plasma in, 971–973
stem cells in, 970–971
Regional anesthesia
intravenous, 152
nerve blocks for
femoral/sciatic, 153
intercostal, 152
RUMM, 152–153
Regonol, for acquired myasthenia gravis, 953*b*
Regurgitation, 365
Rehabilitation. *see* Physical rehabilitation.
Relative knot security, 60, 61*b*
Relaxing incisions, 210–211
multiple punctate, 210, 212*f*
simple, 210, 212*f*
V-to-Y plasty, 210, 212*f*
Z-plasty, 210–211, 212*f*
Release ostectomies, 1035
Release osteotomies, 1035
Remifentanil (Ultiva), 127*t*–131*t*, 133, 144, 148*t*–149*t*
Renal abscesses, 675–677
complications of, 677
definitions for, 675
differential diagnosis of, 676
general considerations and pathophysiology of, 676
medical management of, 676
postoperative care and assessment for, 677
prognosis of, 677
special age considerations for, 677
surgical technique for, 677
surgical treatment of, 676
suture materials and special instrument for, 677
Renal artery, 587*f*, 653–654
ultrasound-guided percutaneous, 654, 655*f*
Renal biopsy, 654–655, 654*b*–655*b*
laparoscopically-guided, 655
surgical, 655, 655*f*
needle, 655
wedge, 655
Renal calculi, 669–673
complications of, 672
definitions for, 669
diagnosis of, 670–671, 670*b*, 671*f*
differential diagnosis of, 671
general considerations and pathophysiology of, 669–670, 670*f*
medical management of, 671
postoperative care and assessment for, 672
prognosis for, 672
special age considerations for, 672
surgical technique for, 672, 672*b*
surgical treatment of, 671–672, 672*b*
suture materials and special instruments for, 672
Renal failure
acute, 650
chronic, 650
defined, 650
Renal hemangioendothelioma, 675*f*
Renal neoplasia, 673–675
complications of, 675
definition for, 673
diagnosis of, 674

Renal neoplasia *(Continued)*
differential diagnosis of, 674
general considerations and pathophysiology of, 673–674, 673*b*–674*b*
medical management of, 674
postoperative care and assessment for, 675
prognosis of, 675
special age considerations for, 675
surgical technique of, 675
surgical treatment for, 674–675, 675*f*
suture materials and special instruments for, 675
Renal pelvis, 653–654
Renal system. *see* Kidney(s); Ureter(s).
Renal vein, 587*f*
Renovations, 23
Repair phase, 180–181
Repetitive nerve stimulation, 1319–1320, 1319*f*
Reproductive surgery, 720–787, 721*b*
anesthesia for, 722–724, 723*t*–726*t*
antibiotics for, 724–725, 726*b*
complications of, 744–746, 744*b*–745*b*
urinary incontinence as, 745, 746*b*
definitions for, 720
females, 746–762
cesarean section as, 735–738
episioplasty (vulvoplasty) as, 740–741, 741*f*
episiotomy as, 738–740, 740*f*
for mammary neoplasia, 746–751
mastectomy as, 738
ovariohysterectomy/ovariectomy as, 728–730, 728*f*, 729*b*, 731*f*–732*f*
laparoscopic-assisted, 730–732, 732*f*
preoperative management of
clinical pathology in, 720, 721*b*
diagnostic imaging in, 721–722, 721*t*
hormone concentrations in, 720–721, 721*t*
other tests in, 722
physical examination in, 720
for pyometra, 752–759
surgical anatomy for, 725–726, 726*b*
for uterine neoplasia, 751–752
for uterine prolapse, 761–762
for vaginal prolapse/hyperplasia/tumor, 759–761
healing after, 743
indication for, 720
males, 762–786
castration as
complications after, 745, 745*b*
cryptorchid, 734, 735*b*, 736*f*
defined, 720
for hypospadias, 775–777
orchiectomy as, 732–743
for paraphimosis, 779–785
for phimosis, 777–779
preoperative management of
diagnostic imaging in, 722
hormone concentrations in, 722
other tests for, 722
physical examination in, 722
Reproductive surgery *(Continued)*
prostatectomy as, 742–743
for prostatic abscess, 764–768
prostatic biopsy as, 742
for prostatic cysts, 768–771
for prostatic neoplasia, 771–772
surgical anatomy for, 726–727, 727*b*–728*b*, 727*f*
for testicular and scrotal neoplasia, 772–775
testicular biopsy as, 741–742
vasectomy as, 735, 737*f*
postoperative care and assessment in, 744
preoperative management of, 720–722, 721*b*
clinical pathology in
female, 720, 721*b*
male, 722
diagnostic imaging in
females, 721–722, 721*t*
male, 722
history in, 720
hormone concentrations in
females, 720–721, 721*t*
males, 722
other tests for
females, 722
males, 722
physical examination in
females, 720
males, 722
special age considerations for, 746
surgical anatomy for, 725–727
females, 725–726, 726*b*
males, 726–727, 727*b*–728*b*, 727*f*
surgical technique for, 728–732, 728*b*
castration as, 745*b*
complications after, 745, 745*b*
cryptorchid, 734, 735*b*, 736*f*
defined, 720
cesarean section as, 735–738
early-age gonadectomy as, 728, 728*b*
episioplasty as, 740–741, 741*f*
episiotomy as, 738–740, 740*f*
mastectomy as, 738
orchiectomy as, 732–743
ovariohysterectomy/ovariectomy as, 728–730, 728*f*, 729*b*, 731*f*–732*f*
laparoscopic-assisted, 730–732, 732*f*
prostatectomy as, 742–743
prostatic biopsy as, 742
testicular biopsy as, 741–742
vasectomy as, 735, 737*f*
suture materials/special instruments in, 743–744, 744*b*
Reproductive tract
female, 725–726, 726*b*
male, 726–727, 727*b*–728*b*
RER (resting energy requirement), 90
Reservoir incontinence, fecal, 507, 507*b*
Resistance, to antibiotics, 79
multidrug, 82–83
Respiratory insufficiency, anesthesia with, 884–886
Respiratory rate, normal, 917*t*
Respiratory system surgery
lower. *see* Lower respiratory system surgery.
Respiratory system surgery *(Continued)*
upper. *see* Upper respiratory system surgery.
Resting energy requirement (RER), 90
Retractor penis muscles, 727
Retractors, 54
hand-held, 54, 54*f*
self-retaining, 54, 54*f*
Retrobulbar blocks, 152
Retrograde cystoscopy, of bladder and urethral neoplasia, 709
Retrograde placement, 958*b*
Retrograde portography, 556
transvenous, 559–560, 560*b*, 560*f*
Retrograde urethrography, of uroliths, 703, 703*b*, 703*f*
Retrohydropropulsion, for bladder and urethral calculi, 703–704, 704*f*
Revascularization, of cancellous bone autografts, 993, 994*f*
Reverse cutting needles, 64, 65*f*
Reverse saphenous conduit flap, 225–226, 226*f*
Rhabdomyosarcomas, of bladder and urethra, 707
Rheumatoid arthritis, 1152–1153
definition for, 1152
diagnosis of, 1152, 1153*f*
differential diagnosis of, 1153
general considerations and clinically relevant pathophysiology, 1152, 1152*b*
medical management of, 1153, 1153*b*
prognosis of, 1153
surgical treatment for, 1153
Rheumatoid factors, 1152
Rhinoplasty, 854, 855*f*
Rhinoscopy, 158, 159*b*, 163
for nasal aspergillosis, 880–881
for nasal tumors, 876
Rhinotomy, 839–841
complications of, 848
defined, 833
with dorsal approach, 840, 840*f*
with intraoral approach, 841, 843*f*
with lateral approach, 840–841, 842*f*
for nasal aspergillosis, 881
for nasal tumors, 878–879
postoperative care for, 848
with ventral approach, 840, 841*f*
Rhythmic stabilization, as therapeutic exercise, 118
Rib fractures, surgical technique for, 899
Rib heads disarticulation, for thoracolumbar spinal trauma, 1422–1423, 1424*f*
Rib tumors, 912
Ribbon retractors, 54, 54*f*
Ribs, 888–889
Rickettsia rickettsii, polyarthritis due to, 1149
Rickettsial polyarthritis, 1149
Rifaximin, for portosystemic shunts, 555
Right angle probe, for arthroscopy, 167, 167*f*
Right atrium, 794–795
Right auricle, 794*f*
Right cerebral hemisphere, 1324*f*

Right colic artery, 468
Right coronary artery, 800–801, 800*f*
Right gastroepiploic artery, 604*f*
Right lateral liver lobe, 543*f*
  complete lobectomy of, 549
Right medial liver lobe, 543*f*
Right ventricle, 794*f*
Right ventricular outflow tract obstruction. *see* Pulmonic stenosis.
Right-angle forceps, 796–797, 796*f*
Right-angled forceps, for lung and thoracic wall surgery, 896–897, 896*f*
Rigid endoscopy
  cannulas for, 158
  defined, 158
  equipment for, 162–163
  flexible *vs*., 160*b*
  indications for, 160
Rigidity
  decerebellate, 1330–1331
  decerebrate, 1330–1331, 1331*f*
Ring, for circular external fixator, 1003
Ring anomalies, vascular. *see* Vascular ring anomalies.
RMSF (Rocky Mountain spotted fever), polyarthritis due to, 1149
Robenacoxib (Onsior), 148*t*–149*t*, 150
Robert Jones bandages, 201–202
  application of, 982, 982*b*, 982*f*
  for temporary fracture stabilization, 981–982
Roccal D Plus, as disinfectant, 20*t*
Rocephin (ceftriaxone), 80*t*
  for Lyme disease, 1150*b*
Rochester-Carmalt hemostat forceps, 53–54, 53*f*
Rocky Mountain spotted fever (RMSF), polyarthritis due to, 1149
Roll, defined, 105
Roll gauze, for outer layer of bandage, 201
ROM (range of motion)
  defined, 116
  passive, 116–117, 117*b*, 117*f*
Rompun (xylazine), for induction of vomiting, for gastric foreign bodies, 418, 418*b*
Rongeurs, 54–55, 55*f*
Root signature, 1330–1331, 1375
Rostrocaudal open-mouth view, 317–318, 317*f*
Rostrotentorial (lateral) craniotomy, 1338, 1343, 1345*f*
Rotational deformity, 1081
Rotational flaps, 218
  for acquired oronasal fistula, 349, 349*b*
  for square and rectangular defects, 215, 216*f*
  for triangular defect, 215, 215*f*
Round ligament, 725–726
RT. *see* Radiation therapy.
Rubrospinal tract, 1332*f*
RUMM nerve blocks (radial, ulnar, musculocutaneous, and median), 152–153
Running suture pattern, 69–70, 70*f*
Rust deposition, on instruments, 55, 57*t*
Rust stain, on instruments, 58*t*
Rutin, for lymphedema, 636, 636*b*
O-(β-hydroxy-ethyl)-Rutosides, for lymphedema, 636

S
Sacculectomy, anal, 487, 487*b*
  definition for, 482
Sacral fracture. *see* Sacroiliac fracture.
Sacral nerves, 689*f*, 727*f*
Sacralization, of lumbar vertebra, 1431
Sacroiliac fracture
  acetabular, 1099–1102
  iliac, ischial, and pubic, 1095
  pelvic, 1092–1095
Sacroiliac joint
  surgical anatomy of, 1093, 1093*f*
  surgical approach to, 1093*f*
Sacroiliac luxation, 1092–1095
Sacrum
  lumbarization of, 1431
  surgical anatomy of, 1428
S-Adenosylmethionine, for cognitive dysfunction syndrome, 1445–1447
Sagittal plane, 1079
Salivary cyst. *see* Salivary mucoceles.
Salivary gland
  excision of, 340
  mandibular, 361, 361*f*
    excision of, 361–363, 362*f*–363*f*
  parotid, 361, 361*f*
    excision of, 363
  sublingual, 361, 361*f*
    excision of, 361–363, 362*f*–363*f*
  surgical anatomy of, 361, 361*b*, 361*f*
  zygomatic, 361, 361*b*, 361*f*
    excision of, 363
Salivary mucoceles, 358–363
  complications of, 363
  definitions for, 358
  diagnosis of, 358–360
    clinical presentation in, 358, 359*b*
    imaging in, 360
    laboratory findings in, 360
    physical examination findings in, 359–360, 360*b*
  differential diagnosis of, 360
  general considerations and clinically relevant pathophysiology, 358, 359*f*
  medical treatment for, 360
  postoperative care and assessment for, 363
  prognosis for, 363
  surgical techniques for, 361–363
    mandibular and sublingual salivary gland excision, 361–363, 362*f*–363*f*
    parotid gland excision, 363
    zygomatic gland excision, 363
  surgical treatment for, 360–361, 360*b*
    anesthesia for, 360–361
    positioning for, 361
    preoperative management of, 360
Salter-Harris classification scheme, of physeal fractures, 984, 984*b*, 985*f*
Santyl, for débridement, 185–186
SAP (serum alkaline phosphatase), high, 28*t*
Sarcomas
  fracture-associated, 1300*t*
  synovial (histiocytic, synovial cell), 1308
Sarcopenia, defined, 105
Sartorius muscle, 520*f*, 527*f*, 686*f*
SAS (subvalvular aortic stenosis)
  diagnosis of, 808–809
  general considerations and clinically relevant pathophysiology, 807
  surgical treatment of, 809, 809*f*
Satinsky clamp, for lung and thoracic wall surgery, 896–897, 896*f*
Satinsky forceps, 53–54
Satinsky vascular clamps, 796–797, 797*f*
Scabs, in wound healing, 179–180
Scaffold (porcine bladder extracellular matrix dressing), 197*t*–198*t*
Scalpels, 50, 51*f*
Scapula, surgical anatomy of, 1048, 1049*f*
Scapular body fractures
  approach to, 1049, 1050*f*
  bone plates and screws in, 1051, 1051*b*
  comminuted, 1051*f*
  fracture assessment score for, 1048, 1048*b*
  orthopedic wire in, 1049, 1049*b*, 1050*f*–1051*f*
  postoperative care and assessment after, 1052
  surgical anatomy for, 1048, 1049*f*
  transverse, 1050*f*–1051*f*
Scapular fractures, 1047–1051
  articular, fracture assessment score for, 1048*b*
  definition for, 1047
  diagnosis of, 1047–1048
  differential diagnosis of, 1048
  general considerations and pathophysiology of, 1047, 1047*b*
  medical management of, 1048
  postoperative care and assessment after, 1052
  prognosis for, 1052
  of scapular body and spine, 1052
  of scapular neck, 1052
  surgical treatment of, 1048, 1048*b*
    anesthesia for, 1048
    approach to scapular neck and glenoid cavity in, 1049, 1049*f*
    approach to scapular spine and body in, 1049, 1050*f*
    bone plates and screws in, 1051, 1051*b*
    complications of, 1052
    fracture assessment score and, 1048, 1048*b*
    Kirschner wires in, 1051, 1051*f*
    orthopedic wire in, 1049, 1049*b*, 1050*f*–1051*f*
    positioning for, 1048
    preoperative management for, 1048
    surgical anatomy for, 1048, 1049*f*
Scapular luxation, 1172–1173
Scapular neck fractures
  bone plates and screws in, 1051, 1051*b*
  Kirschner wires for, 1051, 1051*f*
  lateral approach to, 1049*f*
  surgical anatomy for, 1048, 1049*f*

Scapular spine fractures
approach to, 1049, 1050*f*
bone plates and screws in, 1051, 1051*b*
fracture assessment score for, 1048, 1048*b*
orthopedic wire in, 1049, 1049*b*, 1050*f*–1051*f*
postoperative care and assessment after, 1052
surgical anatomy for, 1048, 1049*f*
Scapulohumeral joint
caudal approach to, 1159
infraspinatus tenotomy for exposure of, 1158–1159
Scapulohumeral joint luxation, 1159–1167
definition for, 1159
diagnosis of, 1159–1162, 1160*f*–1162*f*
differential diagnosis of, 1162
general considerations and clinically relevant pathophysiology, 1159, 1159*b*
medical management of, 1162, 1162*f*
surgical treatment of, 1162–1163
anesthesia for, 1163
complications of, 1167
excision arthroplasty for, 1164, 1166*f*
positioning for, 1163
postoperative care and assessment for, 1166–1167, 1166*f*
preoperative management of, 1163
prognosis, 1167
shoulder arthrodesis for, 1163–1164, 1165*f*–1166*f*
surgical anatomy for, 1163
surgical stabilization of a lateral luxation in, 1163
surgical stabilization of a medial luxation in, 1163, 1164*f*–1165*f*
suture materials and special instruments for, 1164–1166
Scar formation, excess, 194
SCC. *see* Squamous cell carcinoma.
Schiff-Sherrington posture, 1330, 1331*f*
Sciatic nerve, 1096, 1096*b*, 1100
Scissors, 50, 51*f*
Sclera, 282, 289, 289*f*
Sclerosing encapsulating peritonitis (SEP), 527–528
tamoxifen for, 531
Scoliosis, 1328–1330
Scope portal, 158
Scratching activity, Chiari-like malformation with, 1355
Screw(s), bone. *see* Bone screws.
Screw fixation, plate and. *see* Plate and screw fixation.
Screwtails, 252, 254*f*
Scrotal ablation, 734
Scrotal hernias, 522–527
defined, 522
diagnosis of, 523
differential diagnosis of, 523
general considerations and clinically relevant pathophysiology, 522–523
location of, 522*f*
medical management of, 523
surgical treatment for, 523–527
anatomy in, 524, 524*f*
anesthesia, 523–524
Scrotal hernias *(Continued)*
positioning for, 524
postoperative care and assessment in, 527
preoperative management of, 523
prognosis for, 527
suture materials and special instruments for, 527
techniques for, 525–526, 526*f*
Scrotal neoplasia, 772–775
definitions for, 772
diagnosis of, 773–774
differential diagnosis of, 774, 774*b*
general considerations and clinically relevant pathophysiology, 772–773, 773*b*
medical management of, 774
prognosis for, 775
surgical treatment of, 774–775, 774*f*
Scrotal urethrostomy, 689, 691*f*–692*f*
Scrotum
anatomy of, 727
physical examination of, 722
Scrub, surgical. *see* Surgical scrub.
Scrub clothes, 42
Scrub sink area
daily cleaning routines for, 24, 24*b*
description and function of rooms in, 20, 20*f*
Scrub solutions, 44–46, 46*b*, 46*t*
Scrub suits, 42
Scurvy, skeletal (canine), 1296–1297, 1296*b*–1297*b*, 1297*f*
SDFD (superficial digital flexor tendon displacement), 1293
Sebaceous adenoma, 273
Secondary intention, healing by, 193–194
Secondary layer, of wound dressing, 200–201
Secondary palate, 342
Secondary stifle restraints, 1252
Secondary wound closure, 193–194
Second-look arthroscopy, 158
Secur-U clamp, for linear external fixation, 1000, 1000*f*
Seed grafts, 235
Segmental graft, 993
Segmental spinal fixation, modified, for lumbosacral trauma, 1439–1440, 1441*f*
Seidel test, for corneal ulcers, 289
Seizures
after ligation of congenital portosystemic shunt, 563
postmyelographic, 1313
Selegiline (Anipryl, Atapryl, Carbex, Eldepryl, Zelapar), for cognitive dysfunction syndrome, 1445–1447
Self-retaining retractors, 54, 54*f*
Self-tapping screws, 1017
Sella turcica, 597, 599
Semicircular flap, for eyelid mass, 275–276, 277*f*
Seminomas, 773
Semiocclusive dressings, 196, 197*t*–198*t*
Semipermeable film dressing, 197*t*–198*t*
Semitendinosus contracture, 1291
Semitendinosus myopathy, 1291–1293, 1292*f*
Semmelweis, Ignaz Phillip, 43
Senn retractors, 54, 54*f*
Sensory ataxia, 1331–1332, 1332*b*
Sensory nerve conduction velocity, 1319
SEP (sclerosing encapsulating peritonitis), 527–528
tamoxifen for, 531
Septic arthritis, 1146–1149
definition for, 1146
diagnosis of, 1146–1147, 1147*b*, 1147*f*
differential diagnosis of, 1147
general considerations and clinically relevant pathophysiology, 1146
medical management of, 1139–1140, 1140*t*, 1147–1148, 1148*b*
prognosis of, 1149
surgical treatment of, 1148, 1148*b*
Septic peritonitis, 528–529
Septic shock, in peritonitis, 530–531
Sequestrum, 1309
Seroma, 194
elbow, 247–248, 247*f*
treatment of, 247–248, 248*b*
in or under graft, 234
Serosal patching, 447–448, 447*f*–448*f*
Serotonin syndrome, 151
Sertoli cell tumors, 773, 773*b*
Sertoli cells, 772
Serum alkaline phosphatase (SAP), high, 28*t*
Sesamoid bone excision, 1090
Sesamoid bones, 1087
Sesamoid fractures and luxations, 1087–1092
definitions for, 1087
diagnosis of, 1087, 1087*b*
differential diagnosis of, 1087
general considerations and pathophysiology of, 1087
medical management of, 1088
prognosis for, 1092
surgical treatment of, 1088–1090, 1088*f*–1089*f*, 1089*b*
anesthesia for, 1089
complications of, 1092
positioning for, 1090
postoperative care assessment after, 1091–1092
preoperative management of, 1089
surgical anatomy for, 1090, 1090*b*
surgical technique for, 1090–1091
suture materials and special instruments for, 1091
"Setting sun sign", 1348
Sevoflurane, 127*t*–131*t*, 135
for brain surgery, 1340
for liver surgery, 541*t*–542*t*, 542
SGAD (supraglottic airway devices), 135*b*, 136, 136*f*
Shark's tooth forceps, 161, 162*f*
Sharpness, of needle, 64
Shaver, for arthroscopy, 167
Shearing injuries, 1266
of tarsal joints
physical examination findings with, 1267
surgical treatment of, 1269–1270, 1270*b*, 1270*f*

Sheathed needles, for endoscopy, 162
Sheet grafts, 234–235, 235*f*
SHO (sliding humeral osteotomy)
  for medial compartment disease, 1185, 1185*f*
  for osteochondritis dissecans of distal humerus, 1187–1188
Shock
  septic, in peritonitis, 530–531
  spinal, 1336
Shock therapy, in peritonitis, 530–531
Shoe covers, 42
Short bowel syndrome (SBS), 450, 450*b*
Short calcaneofibular ligament, 1268, 1269*f*
Short gastric vessels, ligation of branches of, 402–403, 402*f*
Short medial collateral ligament, 1268, 1269*f*
Short oblique fractures, 983–984
Short tau inversion recovery (STIR) sequences, 169
Shoulder arthrodesis, 1163–1164, 1165*f*–1166*f*
Shoulder instability, 1167–1169
  definition for, 1167
  diagnosis for, 1167–1168, 1167*f*
  differential diagnoses for, 1168
  general considerations and clinically relevant pathophysiology, 1167
  medical management of, 1168
  prognosis of, 1169
  surgical treatment for, 1168–1169
    arthroscopy for, 1168, 1168*f*
    open surgery for, 1169
    postoperative care and assessment for, 1169
    suture materials and special instruments for, 1169
    tightrope stabilization for, 1168–1169, 1169*f*
Shoulder joint
  arthroscopy of, 166*b*
  caudal approach to, 1159
  dislocated. *see* Shoulder luxation.
  infraspinatus tenotomy for exposure of, 1158–1159
  palpation of, 963
  synovial fluid collection from, 1136*f*
Shoulder joint diseases, 1154–1173
  biceps tendon disease as, 1169–1172
  osteochondritis dissecans
    arthroscopic treatment of, 1156–1158
      indications for, 1156
      instrumentation for, 1156, 1156*b*
      portal sites and technique for, 1156–1158, 1157*f*–1158*f*
      postoperative care and assessment for, 1158
    definitions for, 1154
    diagnosis of, 1155–1156, 1155*b*, 1156*f*
    differential diagnosis of, 1156
    general considerations and clinically relevant pathophysiology, 1154–1155, 1155*b*, 1155*f*
    medical management of, 1156
    open surgical techniques for, 1158*b*
      caudal approach for, 1159
      infraspinatus tenotomy for, 1158–1159
Shoulder joint diseases *(Continued)*
      postoperative care and assessment after, 1159
      surgical treatment of, 1156–1158
    prognosis of, 1159
    surgical treatment of, 1156–1158
  scapulohumeral joint luxation as, 1159–1167
  shoulder instability as, 1167–1169
Shoulder luxation, 1159–1167
  definition for, 1159
  diagnosis of, 1159–1162, 1160*f*–1162*f*
  differential diagnosis of, 1162
  general considerations and clinically relevant pathophysiology, 1159, 1159*b*
  medical management of, 1162, 1162*f*
  surgical treatment of, 1162–1163
    anesthesia for, 1163
    complications of, 1167
    excision arthroplasty for, 1164, 1166*f*
    positioning for, 1163
    postoperative care and assessment for, 1166–1167, 1166*f*
    preoperative management of, 1163
    prognosis, 1167
    shoulder arthrodesis for, 1163–1164, 1165*f*–1166*f*
    surgical anatomy for, 1163
    surgical stabilization of a lateral luxation in, 1163
    surgical stabilization of a medial luxation in, 1163, 1164*f*–1165*f*
    suture materials and special instruments for, 1164–1166
Shoulder subluxation. *see* Shoulder instability.
Shunt, ventriculoperitoneal, 1349, 1350*f*
Sialocele. *see* Salivary mucoceles.
Sick sinus syndrome, 825, 826*f*–827*f*, 827
Side cutting needles, 64, 65*f*
Side stepping, as therapeutic exercise, 120
Siderotic plaques, on splenic surface, 637–638
Side-to-side anastomoses, of small intestine, 444–447, 446*f*
Sigmoidoscopes, 162
Silastic gel sheets, 197*t*–198*t*
Silicate uroliths, 701, 702*f*
  signalment of, 702–703, 702*b*
  treatment and prevention of, 702*t*
Silicone elastomer, implantation of, for fecal incontinence, 509, 509*f*
Silicone foam dressings (Cavi-Care), 197*t*–198*t*
Silicone gel sheets (CicaCare), 197*t*–198*t*
Silicone membrane and porcine collagen (Biobrane) dressing, 197*t*–198*t*, 200
Silvadene (silver sulfadiazine), for wound healing, 186
Silvasorb (silver-impregnated dressings), 197*t*–198*t*, 200
Silver sulfadiazine (Thermazene, Silvadene)
  for burns, 239–240
  for wound healing, 186
Silver sulfadiazine solution, for otitis externa, 315, 315*b*
Silvercel (silver-impregnated dressings), 197*t*–198*t*, 200
Silver-impregnated dressings (Acticoat), 197*t*–198*t*, 200
Simple continuous suture pattern, 69–70, 70*f*
Simple interrupted suture pattern, 68–69, 69*f*
Simple relaxing incisions, 210, 212*f*
Single-layer flap repair, for acquired oronasal fistula, 348–349, 350*f*
Single-pedicle advancement flaps, 215, 216*f*
Single-pedicle flaps, 218
Sinonasal aspergillosis. *see* Nasal aspergillosis.
Sinonasal neoplasms. *see* Nasal tumors.
Sinus bradycardia, 825
Sinus venosus, 813
Sinuscopy, for nasal aspergillosis, 881
SIRS (systemic inflammatory response syndrome)
  criteria for diagnosis of, 755*b*
  due to peritonitis, 530–531
SIS (small intestinal submucosa) dressing, 197*t*–198*t*, 200
Sit to stand, as therapeutic exercise, 120
Sit up and beg, as therapeutic exercise, 119–120, 120*b*
SK clamp, for linear external fixation, 1000, 1000*f*
Skeletal muscle, 1281–1282, 1281*f*
Skeletal scurvy, 1296–1297, 1296*b*–1297*b*, 1297*f*
Skeleton
  appendicular, 1299
  axial, 1299

for intestinal resection and anastomosis, 440–447
for serosal patching, 447–448, 447*f*–448*f*
suture materials and special instruments for, 449
volvulus and torsion of, 464–466
Smooth muscles, of periorbita, 268
SMS (spunbond, meltblown, spunbond) wrapping materials, 11–12
Snakebite, 244–246, 244*b*–245*b*
severity score, 245*b*, 245*t*
treatment of, 245–246
Snap 'N' Go #6, as disinfectant, 20*t*
Snap 'N' Go #14, as disinfectant, 20*t*
SOD1 (superoxide dismutase 1) gene, in degenerative myelopathy, 1447
Sodium
high, 28*t*
low, 28*t*
Sodium bicarbonate
for hyperkalemia, 828*b*
for peritonitis, 530–531, 530*b*
Sodium hydroxide, chemical injuries due to, 242
Sodium nitroprusside, for pheochromocytoma, 594–596, 595*t*–596*t*
Soft padded bandages, for temporary fracture stabilization, 983
Soft palate, lateral cleft of, 342
Soft palate defects, closure of, 345
Soft palate hypoplasia, reconstruction of, 345
Soft tissue mass, in brachycephalic syndrome, 852*f*
Soft tissue neoplasms, advanced imaging modalities for, 175, 177*f*
SoftPaws (vinyl nail caps), 257
Solitary nodular density, in pulmonary neoplasia, 901, 902*f*
Soloxine (levothyroxine), for hypothyroidism, 615*b*

Soloxine (thyroid hormone), after hypophysectomy, 599*b*
Solu-Cortef (hydrocortisone), after hypophysectomy, 599*b*
Solugel (hydrogel dressing), 197*t*–198*t*, 198–199
Solutions, pouring into basins of, 16
Somatostatin, for chylothorax, 944
Sorbalgon (calcium alginate dressings), 197*t*–198*t*, 199
Sotalol (Betapace)
  for cardiac disease, 789*b*
  for gastric dilatation-volvulus, 423–424, 425*b*
Spatial relationships, 2*b*
Spatula point needles, 64, 65*f*
Spec cPL and Spec fPL tests, for pancreatitis, 600, 600*b*
Spermatic cord, 524*f*, 727
Sphincter incontinence, fecal, 507, 507*b*
Spica splints, for scapulohumeral joint luxation, 1166–1167
Spica type bandage, 204, 206*f*
Spike activity, on electroencephalography, 1318, 1318*f*
Spike-wave activity, on electroencephalography, 1318, 1318*f*
Spin, defined, 105
Spin lattice relaxation, 169
Spinal arachnoid cyst. *see* Arachnoid diverticulum, spinal.
Spinal arachnoid diverticulum, 1394–1396
  complications of, 1396
  definitions for, 1394
  diagnosis of, 1395, 1395*f*
  differential diagnosis of, 1395
  general considerations and clinically relevant pathophysiology, 1394
  medical management of, 1395
  prognosis of, 1396
  surgical treatment of, 1395–1396, 1396*f*
Spinal cord, healing of, 1373–1374
Spinal locking plate, for cervical spondylomyelopathy, 1385, 1387*f*
Spinal neoplasia
  cervical, 1396–1399
    complications of, 1398
    definitions for, 1396
    diagnosis of, 1397–1398, 1397*f*
    differential diagnosis of, 1398

skin, 970
Stem cell niche, 970
Stenotic nares, 849, 850*f*
resection, 854, 855*f*
Sterile, defined, 2*b*
Sterile container systems, opening of, 16, 17*f*
Sterile field, 2*b*
Sterile instrument room, 19
Sterile meningitis, 1455
Sterile packs
handling and storage of, 13–16
damage during, 13–14
for sterile container systems, 16, 17*f*
sterile shelf life in, 13
unwrapping and opening of, 14, 16, 16*f*
preparation of, 10–13, 11*b*, 13*b*
folding and wrapping drapes in, 13, 15*f*
folding and wrapping gowns in, 13, 15*f*
packaging materials for
based on device type, 11–12, 12*t*
sterilization method, 8–9, 9*t*
wrapping instrument packs in, 13, 14*f*
wrapping materials for, 12, 12*t*
Sterile shelf life, 13

Sterile skin preparation, 38–39, 38*b*
alcohol-based solutions as, 38–39, 38*t*, 39*b*
characteristics of ideal, 38, 38*b*
chlorhexidine as, 38, 38*t*
povidone-iodine as, 38, 38*t*, 39*f*
prevention of pooling of alcohol with, 39*b*
properties of, 38, 38*t*
purpose of, 38
Sterile technique
aseptic technique *vs.*, 1
defined, 1, 2*b*
principles of, 2, 2*b*, 3*t*
Sterility, during surgery, 48–49
Sterilization, 2, 3*t*
advantages and disadvantages for, 4
chemical (gas), 5–7
ethylene oxide for, 5–7, 6*t*, 9*f*, 11*f*
cold chemical, 10
defined, 4–10
equipment for, 8*f*
indicators for, 10–13, 10*f*–11*f*
ionizing radiation for, 9–10
level of, 3*t*
high-, 2*b*
low-temperature, 4
peracetic acid, 9
plasma, 6*t*, 7–9
tape and indicator strips for, 11*f*
steam, 4, 6*t*
gravity displacement sterilizer, 4–5, 7*f*, 7*t*
immediate-use, 4–5
prevacuum, 4
tape and indicator strips for, 10*f*
types of, 4–5
sterilants used in, 4, 5*t*
Sterilization wraps, 11–12
Sterilized instruments
handling and storage of, 13–16
packaging materials for
based on device type, 11–12, 12*t*
sterilization method, 8–9, 9*t*
sterile shelf life in, 13
unwrapping and opening of, 14
for large sterile linen/paper/polypropylene packs that cannot be held during distribution, 14
from sterile container systems, 16, 17*f*
for sterile items in paper/plastic or plastic peel-back pouches, 16, 16*f*
for sterile linen/paper packages that can be held during distribution, 14–16, 16*f*
wrapping materials for, 12, 12*t*
Sterillium Rub, for surgical scrub, 44–46
Sternal saw, for median sternotomy, 892–893, 892*f*
Sternectomy, partial, for thoracic wall neoplasia, 913–914
Sternocephalicus muscle, 1369*f*
Sternohyoideus muscle, 839*f*, 1369*f*
Sternothyroideus muscle, 839*f*
Sternotomy, median
definition for, 884
surgical technique for, 891–893, 892*f*–893*f*
Sternum
healing of, 895–896
surgical anatomy of, 888–889
Steroid-responsive meningitis-arteritis, 1455–1456
Steroids, synthetic, for benign prostatic hyperplasia, 763–764
Stifle joint
lateral approach to, 1234, 1235*f*
medial approach to, 1235, 1236*f*
palpation of, 963–964, 964*f*
synovial fluid collection from, 1136*f*
Stifle joint diseases, 1227–1266
caudal cruciate ligament injury as, 1248–1250
collateral ligament injury as, 1250–1252
cranial cruciate ligament rupture, 1227–1243
meniscal injury as, 1243–1248
multiple ligament injuries as, 1252–1254
osteochondritis dissecans as, 1264–1266
definition for, 1264
diagnosis of, 1264–1265, 1265*f*
differential diagnosis of, 1265
general considerations and clinically relevant pathophysiology, 1264
medical management of, 1265
prognosis of, 1266
surgical treatment for, 1265–1266
patellar luxation as
lateral, 1261–1264
medial, 1254–1261
Stifle restraints
primary, 1252
secondary, 1252
STIR (short tau inversion recovery) sequences, 169
Stitch scissors, 50, 51*f*
Stomach, 398–433
anesthetic considerations for, 399, 399*t*–400*t*
antibiotics for, 399
benign gastric outflow obstruction of, 425–427
complications in, 416
dilatation-volvulus of, 419–424
foreign bodies in, 416–419
definition for, 416
diagnosis of, 417–418
clinical presentation in, 417
imaging in, 417–418, 418*b*
laboratory findings in, 418
physical examination findings in, 417, 417*b*
differential diagnosis of, 418
general considerations and clinically relevant pathophysiology, 416–417, 416*b*–417*b*, 417*f*
medical management of, 418, 418*b*
postoperative care and assessment for, 419, 419*b*
prognosis for, 419
surgical technique for, 418
surgical treatment of, 418
anesthesia for, 418
positioning for, 418
preoperative management of, 418
surgical anatomy for, 418
Stomach *(Continued)*
suture materials and special instruments for, 418
healing of, 415
neoplasia and infiltrative disease of, 430–433
postoperative care and assessment for, 416
preoperative concerns in, 398
prognosis for, 416
special age considerations for, 416
surgical anatomy of, 399–400, 400*b*
surgical techniques for, 400–415
gastropexy as, 406–415, 406*b*
gastroscopy as, 400–401
gastrotomy as, 401, 401*f*
partial gastrectomy and invagination of gastric tissue as, 402–403, 402*b*, 402*f*
partial gastrectomy with gastrojejunostomy (Billroth II) as, 403, 405*f*
pylorectomy with gastroduodenostomy (Billroth I) as, 403, 403*b*, 404*f*
pyloromyotomy and pyloroplasty as, 403–406, 405*b*
temporary gastrostomy as, 403
suture materials and special instruments in, 415–416
ulceration and erosion of, 427–430
Stool softeners
after large intestinal surgery, 474, 474*b*
after prostatic or perineal surgery, 744*b*
Strabismus, 1325, 1327*f*
due to hydrocephalus, 1348, 1348*f*
Straight needle, 64, 65*f*
Straight-pull tensile strength, 61*b*
Strains
at fracture site, 1025–1026
muscle-tendon unit, 1280–1282
definitions for, 1280
diagnosis of, 1280, 1281*f*
differential diagnosis of, 1280
general considerations and clinically relevant pathophysiology, 1280
medical management of, 1281
physical rehabilitation for, 1281, 1281*b*
prognosis of, 1282
surgical treatment of, 1281–1282, 1281*f*
Strangle knot, 71–72, 72*f*
Stranguria, 720
Streptokinase, for pulmonary thromboembolism, 888*b*
Streptozotocin, for insulinomas, 610
Stretch reflex, 1334
Stretch rings, for circular external fixators, 1003
Stretching exercises, 116–117, 117*b*, 117*f*
Strictures, esophageal, 380–383
definition for, 380
diagnosis of, 381
clinical presentation in, 381
imaging in, 381, 381*f*
laboratory findings in, 381
physical examination findings in, 381
differential diagnosis of, 381–382
endoscopic dilation of, 160, 162

Strictures, esophageal *(Continued)*
general considerations and clinically relevant pathophysiology, 380–381, 380*b*
medical treatment of, 382
postoperative care and assessment of, 383
prognosis for, 383
surgical techniques for, 382–383
balloon dilation, 382–383, 382*b*
bougienage, 382, 382*b*
surgical treatment of, 382
anesthesia for, 382
positioning for, 382
preoperative management of, 382
suture materials and special instruments for, 383
Strip grafts, 235
Stroke, defined, 1448
Stromal corneal ulcer, 286
Stromal vascular fraction, 968–970
Struvite uroliths, 670, 701, 702*b*
imaging of, 703, 703*f*
signalment of, 702, 702*b*
treatment and prevention of, 702*t*
Stump pyometra, 752
Stupor, 1323, 1324*t*
Styloid process fractures, 1076*f*
Subaortic stenosis
anesthetic considerations for, 792*t*–793*t*
cardiovascular parameters for, 790*t*
Subchondral bone, 1141–1142, 1142*f*
Subcutaneous emphysema, 897–898
Subcutaneous sutures, 68, 68*f*
Subcutaneous ureteral bypass system, 662, 673, 673*f*
Subcuticular sutures, 68, 68*f*
Subcutis, 179
Subdermal plexus, 179
Subdermal plexus flaps, 217
Subdermal sutures, 208
Sublimaze. *see* Fentanyl citrate.
Sublingual mucocele, 358, 359*f*
Sublingual salivary duct, 361*b*
Sublingual salivary gland, 361, 361*f*
excision of, 361–363, 362*f*–363*f*
Subluxation(s), 958*b*
angle of, 1209, 1210*f*
carpal, 1202–1206
defined, 1266
elbow
caused by premature closure of the distal ulnar or radial physes, 1197–1200
definition for, 1197
differential diagnosis of, 1198
general considerations and clinically relevant pathophysiology, 1197–1198, 1197*b*, 1198*f*
medical management of, 1198
prognosis for, 1200
surgical treatment for, 1198
anesthesia for, 1198
complications of, 1200
positioning for, 1198
postoperative care after, 1200, 1200*b*
Subluxation(s) *(Continued)*
preoperative management of, 1198
radial lengthening for, 1199
surgical anatomy for, 1198
suture materials and special instruments for, 1199
ulnar-lengthening osteotomy for, 1198–1199, 1199*b*, 1199*f*
proximal intertarsal, 1267–1268, 1268*f*
shoulder. *see* Shoulder instability.
Suboccipital craniotomy, 1338, 1344, 1347*f*
Subpapillary plexus, 179
Subpubic urethrostomy, 692–694, 694*f*–695*f*
Subserosa, 918–920
Subsinuosal interventricular branch, 800–801
Substantia gelatinosa (lamina II), 140
Subtotal coronoidectomy
arthroscopic, 1178, 1179*f*
for medial compartment disease, 1185
open, 1180
Subtotal epiglottectomy, 863–864
Subvalvular aortic stenosis (SAS)
diagnosis of, 808–809
general considerations and clinically relevant pathophysiology, 807
surgical treatment of, 809, 809*f*
Sucralfate (Carafate)
after foreign body removal, 166
for gastric ulceration and erosion, 429, 429*b*
for gastrinomas, 613, 613*b*
Suction tips, 54–55, 54*f*
Suction unit, 22, 22*f*
Sugar, for wound healing, 188
Sulfuric acid, chemical injuries due to, 242
Superficial brachial artery, 223*f*
Superficial brachial axial pattern flap, 224
Superficial burns, 237
Superficial cervical axial pattern flap, 223–224
Superficial cervical lymph nodes, 631, 632*f*
Superficial corneal ulcer, 286
Superficial digital flexor muscle, 1075*f*
Superficial digital flexor tendon displacement (SDFD), 1293
Superficial gluteal muscle, 1112*f*
Superficial inguinal lymph nodes, 631, 632*f*
Superficial inguinal ring, 520*f*
Superficial lateral caudal artery, 223*f*
Superficial pectoralis muscle, 1055*f*
Superficial skin infection, 36–37
Superficial temporal artery, 223*f*
Superficial temporal artery axial pattern flap, 223
Superficial zone, of articular cartilage, 1141–1142, 1142*f*
Superoxide dismutase 1 (SOD1) gene, in degenerative myelopathy, 1447
Support rods, for outer layer of bandage, 201
Supporting ligaments, 1141*f*
Suppurative arthritis. *see* Septic arthritis.
Supracondylar fractures
femoral, 1102–1109
definitions for, 1102
diagnosis of, 1103
Supracondylar fractures *(Continued)*
differential diagnosis of, 1103
general considerations and pathophysiology of, 1102–1103
medical management of, 1103
prognosis for, 1109
surgical treatment of, 1103–1104, 1103*b*
anesthesia for, 1103
complications in, 1109, 1110*b*
positioning for, 1104
postoperative care and assessment after, 1108, 1110*t*
preoperative management of, 1103
surgical anatomy for, 1103–1104, 1103*b*
surgical approach for, 1104, 1104*f*
suture materials and special instruments for, 1108
humeral, surgical treatment of, 1059, 1060*f*
Supraglenoid tuberosity, avulsion fractures of, 1052
Supraglottic airway devices (SGAD), 135*b*, 136, 136*f*
Supramid (polymerized caprolactam) sutures, 62, 63*t*
Suprascapular nerve, 1049*f*
Supraspinatus muscle, 1049*f*
Supraspinatus tendinopathy, 1286–1288
definition for, 1286
diagnosis of, 1287
differential diagnosis of, 1287
general considerations and clinically relevant pathophysiology, 1287
medical management for, 1287
physical rehabilitation for, 1287
postoperative care for, 1288
prognosis of, 1288
surgical treatment for, 1288
Suprax (cefixime), 80*t*
Surefuser constant-rate delivery system, for ear surgery, 302, 303*b*
Surfaces, in operating room, 21
Surgeon, 23
Surgeon's knot, 71–72, 72*f*
Surgery
for esophageal foreign body removal, 379–380
maintaining sterility during, 48–49
Surgical adhesive tape, for outer layer of bandage, 201
Surgical area
care and maintenance of, 23
daily cleaning routines for, 23–25
for anesthesia and patient preparation room, 24–25, 24*b*
for operating room, 23–24, 24*b*
for recovery room, 25
for scrub sinks, 24, 24*b*
weekly and monthly cleaning routines for, 25
description and function of rooms in, 19–23
anesthesia and surgical preparation areas, 19, 19*b*, 20*t*
anesthesia supply room as, 19
dressing room as, 19

Surgical area *(Continued)*
equipment room as, 19–20
gowning and gloving area as, 21, 21*b*
housekeeping supply room as, 20
minor procedures surgery room as, 23
nurses' workstation as, 19
operating room as, 21–22
instrument table in, 22
lighting for, 21, 21*f*
operating table in, 21–22, 22*f*
suction in, 22, 22*f*
postoperative recovery area as, 23
scrub sink area as, 20, 20*f*
sterile instrument room as, 19
disinfectants for, 20*t*
exclusion of paw from, 37, 37*f*
food and drink in, 18
personnel in, 23
repairs and renovations of, 23
room "turnover" for, 22–23
structure and design of, 18–25, 18*b*
traffic patterns through, 18, 19*b*
Surgical asepsis
handling and storage of, 13–16
damage during, 13–14
for sterile container systems, 16, 17*f*
sterile shelf life in, 13
unwrapping and opening of, 14
for large sterile linen/paper/polypropylene packs that cannot be held during distribution, 14
for sterile items in paper/plastic or plastic peel-back pouches, 16, 16*f*
for sterile linen/paper packages that can be held during distribution, 14–16, 16*f*
pouring solutions into basins, 16
preparation of, 10–13, 11*b*, 13*b*
folding and wrapping drapes in, 13, 15*f*
folding and wrapping gowns in, 13, 15*f*
packaging materials for
based on device type, 11–12, 12*t*
sterilization method, 8–9, 9*t*
wrapping instrument packs in, 13, 14*f*
wrapping materials for, 12, 12*t*
principles of, 1–3
sterile technique for, 2, 2*b*, 3*t*
sterilization and disinfection in, 2, 3*t*

organic, 62
synthetic, 62–64
removal of, 74, 194
selection by tissue type of, 65–66
for abdominal closure, 65
for hollow viscous organs, 66
for infected or contaminated wounds, 66
for muscle and tendon, 65
for parenchymal organs, 66
for skin, 65
for vessels and vascular anastomoses, 66, 66*f*–67*f*
selection of, 60–66
subdermal, 208
tension, for skin stretching and expansion, 207–208, 209*f*
walking, 209, 210*f*
wound healing and, 190
Suture patterns, 68, 208–210
appositional, 68
continuous, 69–71
Connell, 70–71, 70*f*
Cushing, 70–71, 70*f*
Ford interlocking, 70, 70*f*
Lembert, 70, 70*f*
running, 69–70, 70*f*
simple, 69–70, 70*f*
everting, 68
external tension-relieving, 209–210
interrupted, 68–69
cruciate, 69, 69*f*
Gambee, 69, 69*f*
Halsted, 69
horizontal mattress, 69, 69*f*
simple, 68–69, 69*f*
vertical mattress, 69, 69*f*
inverting, 68
Suture patterns *(Continued)*
subcutaneous and subcuticular, 68, 68*f*
subdermal, 208
tendon, 71
Bunnell, 71, 71*f*
far-near-near-far, 71, 71*f*
three-loop pulley, 71, 71*f*
walking, 209
Suture pullout value, 61*b*
Suture repair of luxations, 1090–1091
Suture scissors, 50, 51*f*
Suture stabilization, for caudal cruciate ligament injury, 1249, 1249*f*
Sutured anastomoses
of large intestine, 471
of small intestine, 440–444, 442*f*
with intestinal segments of disparate size, 440–441, 442*f*
modified simple continuous pattern for, 441–443, 443*f*
Sutured laparoscopic gastropexy, 410
intracorporeally, 411–414
Suturing, 60–78
needles for, 64, 65*f*
prevention of "dog ears" in, 210, 211*f*
techniques for, 68
Swallowing reflex, 1325–1328, 1329*f*
Swenson's pull-through procedure, 486
Swimming, as aquatic therapy, 122–123, 123*f*
Symphyseal fractures, mandibular, 1045, 1046*f*
Synercid (dalfopristin and quinupristin), as drug of last resort, 82–83
Synovial cell sarcoma, 1308
Synovial fluid, 1141
Synovial fluid collection, in arthropathies, 1135–1137, 1136*f*, 1137*b*
Synovial joints, 1134, 1141, 1141*b*, 1141*f*
Synovial membrane, 1134, 1141, 1141*f*
Synovial myxomas, 1308
Synovial sarcomas, 1308
Synovioma, malignant, 1308
Synovitis, inflammatory, 1145
Synthetic surgical mesh, 68
Synthetic sutures
absorbable, 61–62
nonabsorbable, 62–64
sizes of, 61*t*
Synthroid (thyroid hormone), after hypophysectomy, 599*b*
Syringomyelia, 1389
Chiari-like malformation with, 1353–1354, 1354*f*
Systemic inflammatory response syndrome (SIRS)
criteria for diagnosis of, 755, 755*b*
due to peritonitis, 530–531
Systemic venous pressure, normal, 558, 558*b*

T

T1 relaxation, 169
T1-weighted image, 169
T2 relaxation, 169
T2-weighted image, 169
T_3 (triiodothyronine), 615
suppression test, 619, 619*b*
T_4 (thyroxine), 615
free, 618–619, 619*b*
total, 618–619
T8 solution, for otitis externa, 315*b*
Tacrolimus, for perianal fistula, 503, 503*b*
Tactile placing, 1333–1334, 1333*f*
Tail docking, 253–254
Tail fold resection, 252–253
Tail folds, 252–253, 254*f*
Talar fractures
of talar neck, 1086, 1086*f*
trochlear, 1086
Talar neck fractures, 1086, 1086*f*
Talus, 1085–1086
Tamoxifen, for peritonitis, 531
Tangential vascular clamps, 796–797, 797*f*
Tap water, as wound cleanser, 184, 184*t*, 188
Tapazole (methimazole), for feline hyperthyroidism, 619–620, 620*b*
preoperative, 620–621, 620*b*
Tape muzzle, for displaced mandible, 1037, 1037*f*
Tapercut needles, 64, 65*f*
Taperpoint needles, 64, 65*f*
Tapping, as neurologic rehabilitation exercises, 122
Tar, chemical injuries due to, 242
Tarsal arthrodesis, partial, 1270, 1270*f*
Tarsal fractures, 1084–1087
definitions for, 1084
diagnosis of, 1084
differential diagnosis of, 1085
general considerations and pathophysiology of, 1084
medical management of, 1085
prognosis for, 1087
radial, 1084
stabilization of, 1086
surgical anatomy of, 1085–1086
surgical treatment of, 1085–1086, 1085*f*
anesthesia for, 1085
complications of, 1087
positioning for, 1086
postoperative care and assessment after, 1086–1087
preoperative management of, 1085
surgical anatomy for, 1085–1086
surgical techniques for, 1086
suture materials and special instruments for, 1086
Tarsal joint, imaging of, 1267*f*
Tarsal joint disease, 1266–1277
ligament injury as, 1266–1272
definition for, 1266
diagnosis of, 1267, 1267*b*, 1267*f*–1268*f*
differential diagnosis of, 1267
general considerations and clinically relevant pathophysiology, 1266–1267
medical management of, 1267
prognosis of, 1272
surgical treatment for, 1267–1269
anesthesia for, 1268
complications of, 1271
partial tarsal arthrodesis in, 1270, 1270*f*
positioning for, 1268–1269
postoperative care after, 1271

Tarsal joint disease *(Continued)*
preoperative management of, 1268
shearing injuries in, 1269–1270, 1270*b*, 1270*f*
surgical anatomy for, 1268, 1269*f*
suture materials and special instruments for, 1271
tarsocrural joint arthrodesis (pan tarsal arthrodesis), 1270–1271, 1271*f*
tarsocrural luxation or subluxation in, 1268*f*–1269*f*, 1269
tarsometatarsal luxation in, 1270, 1271*f*
osteochondritis dissecans as, 1272–1277
definition for, 1272
diagnosis of, 1272
arthroscopy in, 1272, 1273*f*
clinical presentation in, 1272, 1272*b*
imaging in, 1272, 1272*b*, 1272*f*–1273*f*
physical examination in, 1272
differential diagnosis of, 1272–1274
general considerations and clinically relevant pathophysiology, 1272
medical management of, 1274
prognosis for, 1276–1277, 1277*b*
surgical treatment of, 1274
anesthesia for, 1274
arthroscopy in, 1274
arthrotomy in, 1274
dorsolateral approach to, 1275
dorsomedial approach to, 1274
plantarolateral approach to, 1275–1276, 1276*f*
plantaromedial approach to, 1274, 1275*f*
positioning for, 1274
postoperative care after, 1276
preoperative management of, 1274
surgical anatomy for, 1274
suture materials and special instruments for, 1276
Tarsocrural joint arthrodesis, 1270–1271, 1271*f*
Tarsocrural joint luxation
physical examination findings in, 1267
surgical treatment and, 1267, 1268*f*–1269*f*, 1269
Tarsometatarsal luxation, 1268, 1270, 1271*f*
Tarsorrhaphy
definition for, 294
permanent lateral, for ectropion and entropion, 279–280, 280*f*
temporary, for eyelid surgery, 269, 270*f*
Tarsus
arthroscopy of, 166*b*
surgical anatomy of, 1268, 1269*f*
TBSA (total body surface area), 238–239, 239*t*
TCCs. *see* Transitional cell carcinomas.
TE. *see* Therapeutic exercise.
TECA. *see* Total ear canal ablation.
Teflon (polytetrafluoroethylene) injection, for urinary incontinence, 714
Tegaderm (polyurethane film dressing), 197*t*–198*t*, 200
Tegagel (hydrogel dressing), 197*t*–198*t*, 198–199
Telazol, for premedication, 132*b*, 134–135
Telescopes, in rigid endoscopy, 158
Telfa Pads (rayon/polyethylene glycol dressing), 197*t*–198*t*
Temperature, of operating room, 21
Temperature-time graph, for sterilization, 10
Temporal sinus, 1343*f*
Temporalis muscle flap, 231, 232*f*
Temporary carotid artery ligation, 334, 334*b*
Temporary epiglottopexy, 864
Temporary transvenous pacing, for bradycardia, 828
Temporomandibular joint fractures
open reduction of, 1044–1045, 1045*f*
surgical approach to, 1043, 1045*f*
Tendon(s)
healing of, 1283
materials for, 65
repair of, stem cells for, 973
Tendon injury or disease, 1280–1294
Achilles tendon rupture as, 1284–1286
muscle-tendon unit contusion and strains as, 1280–1282
muscle-tendon unit laceration as, 1282–1284
superficial digital flexor tendon displacement as, 1293
supraspinatus tendinopathy, 1286–1288
Tendon laceration, 1282–1284
definition for, 1282
diagnosis of, 1282
differential diagnosis of, 1282
general considerations and clinically relevant pathophysiology, 1282
healing of, 1283
medical management of, 1282
physical rehabilitation for, 1282, 1284
prognosis of, 1284
surgical treatment of, 1282–1283
anesthesia for, 1283
positioning for, 1283
postoperative care after, 1283–1284
preoperative management of, 1282
surgical anatomy for, 1283
surgical technique for, 1283, 1283*f*
suture materials and special instruments for, 1283, 1283*f*
Tendon reflex, 1334
Tendon rupture, 1284–1286
definitions for, 1284
diagnosis of, 1284–1285, 1284*f*
differential diagnosis of, 1285
general considerations and clinically relevant pathophysiology, 1284
medical management of, 1285
postoperative care for, 1286, 1286*f*
prognosis of, 1286
surgical treatment for, 1285
Tendon sutures, patterns for, 71
Bunnell, 71, 71*f*
far-near-near-far, 71, 71*f*
three-loop pulley, 71, 71*f*
Tenesmus, 466
Tenodesis, of popliteal tendon, for caudate cruciate ligament injury, 1250
Tenormin (atenolol), for cardiac disease, 789*b*
Tenosynovitis, bicipital, 1169–1170
Tensile strength
knot, 60
knot-pull, 61*b*
straight-pull, 61*b*
Tensilon test, for laryngeal paralysis, 860*b*
Tension bands
for intramedullary fixation, 1015–1016
application of, 1015–1016, 1016*b*
equipment and supplies for, 1015
indications and biomechanical principles of, 1015, 1015*f*
postoperative care for, 1016
for malleolar fractures, 1129–1130, 1130*f*
for olecranon osteotomy, 1063
for supraglenoid tuberosity avulsions, 1051*f*
for transverse calcaneal fractures, 1085*f*
for trochanteric physeal fracture, 1117
Tension lines, 205–206, 207*f*
incision across, 207*f*
manipulation of wound edges along, 205–206, 207*f*
Tension pneumothorax, 933
Tension relief, 206, 208*f*
Tension sutures, for skin stretching and expansion, 207–208, 209*f*
Tension-relieving esophageal myotomy, 371–373, 373*f*
Tension-relieving sutures, external, 209–210
Tensor bandaging, in neurologic rehabilitation exercises, 122
Tensor fasciae latae muscle, 1112*f*
Tepoxalin (Zubrin), 148*t*–149*t*, 150
Teres minor muscle, 1049*f*–1050*f*, 1063*f*
Terminal sterilization and disinfection, 2*b*
Territorial infarcts, 1448
Tertiary layer, of wound dressing, 201
Testicles
anatomy of, 727
biopsy of, 741–742
palpation of, 722
Testicular biopsy, 741–742
complications of, 745*b*
Testicular neoplasia, 772–775
definitions for, 772
diagnosis of, 773–774
differential diagnosis of, 774, 774*b*
general considerations and clinically relevant pathophysiology, 772–773, 773*b*
medical management of, 774
prognosis for, 775
surgical treatment of, 774–775, 774*f*
Testicular torsion, 774–775, 774*f*
Testis(es). *see* Testicles.
Testosterone, in males, 722
Testosterone cypionate (Depo-Testosterone), for urinary incontinence, 713–714, 714*b*, 746*b*
Tetracyclines, 81–82, 81*b*

Tetralogy of Fallot, 815–817
acyanotic or pink, 815
definitions for, 815
diagnosis of, 815–816
differential diagnosis of, 816
general considerations and clinically relevant pathophysiology, 815
medical management of, 816
prognosis for, 817
surgical treatment of, 816, 816*f*
Tetraparesis, 1332, 1365
Tetraplegia, 1332, 1365
TFAST (thoracic focused assessment with sonography for trauma), 29, 29*b*, 30*f*
T-fractures of elbow, stabilization of, 1065, 1066*f*
Thalamic/midbrain infarcts, 1448
Thalamus, 1324*f*
Thenar grip, 52–53, 52*f*
Theophylline (extended release), for tracheal collapse, 871*b*
Therapeutic antibiotics, for surgical infection, 79, 86–88, 88*b*
Therapeutic exercise (TE), 117–121, 118*f*
backwards walking as, 120
balance and proprioceptive as, 118–120
balance boards, balance discs, BOSU ball as, 118, 119*f*
ball work as, 119
Cavaletti course as, 118–119, 119*f*
core strengthening as, 119
crawling as, 119
diagonal leg lifts as, 120, 120*f*
digging as, 121
equipment required for, 118, 118*t*
figure eights as, 119
front limb, 121
high-five salute as, 121
hind limb, 120–121
incline walking as, 120
ladder walking as, 121
planking on blocks and balls as, 119
play bow as, 121
rhythmic stabilization/weight shifting as, 118
side stepping as, 120
sit to stand as, 120
sit up and beg as, 119–120, 120*b*
stairs in, 121
standing, 118
with elevated front legs, 120–121
weave cones as, 119, 120*f*
weight shifting, unsteady surface as, 118
wheelbarrow as, 121
Therapeutic ultrasound, 112–113, 112*f*, 113*b*
Thermal injuries. *see* Burns.
Thermal therapy, 111–112, 112*b*
Thermazene (silver sulfadiazine)
for burns, 239–240
for wound healing, 186
Thiopental (Pentothal)
for brain surgery, 1340
for induction, 127*t*–131*t*, 133
Third eyelid, healing of, 283
Third eyelid flap, 283, 284*f*
Third eyelid gland, 282
Third eyelid gland prolapse, 284–286
complications of, 286
definition for, 281, 284
diagnosis of, 285
clinical presentation in, 285
laboratory findings in, 285
physical examination findings in, 285
differential diagnosis of, 285
general considerations and clinically relevant pathophysiology, 284–285
medical management of, 285
postoperative care and assessment for, 286
prognosis for, 286
surgical techniques for, 285–286, 286*b*, 286*f*
surgical treatment for, 285
anesthesia for, 285
positioning for, 285
preoperative management, 285
surgical anatomy for, 285
suture materials and special instruments for, 286
Third eyelid surgery, 281–291
anesthetic considerations in, 281–282
antibiotics in, 282, 282*b*
complications in, 284
postoperative care and assessment in, 284
preoperative concerns in, 281, 281*b*
special age considerations in, 284
surgical site preparation in, 281, 281*b*
third eyelid flap in, 283, 284*f*
Third-degree burns, 238, 238*f*
Thoracentesis
definition for, 916
needle, 920–922, 921*f*
Thoracic diseases, advanced imaging modalities for, 175
Thoracic duct ligation, 945–946
thoracoscopic, 945–946, 946*b*
Thoracic empyema. *see* Pyothorax.
Thoracic focused assessment with sonography for trauma (TFAST), 29, 29*b*, 30*f*
Thoracic spine. *see also* Thoracolumbar spine.
dorsal approach to cranial and mid, 1405–1406, 1405*f*–1406*f*
Thoracic suction, continuous, 924, 925*f*–926*f*
Thoracic vertebrae, 1404–1405
Thoracic wall diseases, advanced imaging modalities for, 175
Thoracic wall metastases, imaging of, 1301*b*
Thoracic wall neoplasia, 912–914
clinical presentation of, 912
definitions for, 912
diagnosis of, 912
diagnostic imaging of, 912
differential diagnosis of, 912
general considerations and clinically relevant pathophysiology, 912
laboratory findings in, 912
medical management of, 912–913, 913*f*
physical examination findings in, 912
prognosis of, 914
surgical treatment of, 913
anesthesia for, 913
Thoracic wall neoplasia *(Continued)*
complications with, 914
en bloc resection for, 913, 914*f*
partial sternectomy for, 913–914
positioning for, 913
postoperative care and assessment for, 914
preoperative management of, 913
suture materials and special instruments for, 914
Thoracic wall surgery, 884–915
anesthesia for, 884–888, 885*t*–886*t*, 886*b*–887*b*
antibiotics for, 888
complete lobectomy for, 894–895, 896*f*
complications of, 897, 897*b*
definitions for, 884
healing after, 895–896
lung biopsy for, 893–894
for lung lobe torsion, 905–907
partial lobectomy for, 894, 895*f*
for pectus excavatum, 907–912
postoperative care and assessment for, 897, 897*b*
preoperative management of, 884, 884*b*
for pulmonary abscesses, 903–905
for pulmonary neoplasia, 900–903
special age considerations for, 897
surgical anatomy for, 888–889, 889*f*–890*f*
surgical materials and special instruments for, 896–897, 896*f*
for thoracic wall neoplasia, 912–914
for thoracic wall trauma, 897–900
thoracotomy for, 889–893, 889*b*, 889*t*
Thoracic wall trauma, 897–900
clinical presentation of, 898
definition for, 897
diagnosis of, 898–899
diagnostic imaging of, 898–899, 899*b*
differential diagnosis of, 899
general considerations and clinically relevant pathophysiology, 897–898, 897*f*–898*f*
laboratory findings in, 899
medical management of, 899
physical examination findings in, 898
postoperative care and assessment for, 899
prognosis of, 899–900
surgical treatment of, 899
suture materials and special instruments for, 899
Thoracoabdominal (TA) stapler, for partial lobectomy, 894, 895*f*
Thoracocentesis. *see* Thoracentesis.
Thoracodorsal artery, 223*f*
Thoracodorsal axial pattern flap, 224, 224*b*, 224*f*
Thoracolumbar disc disease, 1410–1415
complications in, 1414
definitions for, 1410
diagnosis of, 1410–1412, 1412*f*
differential diagnosis of, 1412
general considerations and pathophysiology of, 1410, 1411*f*
medical management of, 1412–1413
postoperative care and assessment in, 1414

Thoracolumbar disc disease *(Continued)*
prognosis for, 1414–1415
surgical treatment of, 1413, 1413*f*–1414*f*
suture materials and special instruments for, 1414
Thoracolumbar spine
dorsal, 1406–1408, 1407*f*
elevation of the multifidus musculature in, 1406–1408, 1407*f*
pediculectomy in, 1404, 1408, 1408*f*
positioning for, 1406–1408, 1407*f*
removal of attachments of multifidus musculature in, 1406–1408, 1407*f*
dorsal approach to cranial and midthoracic spine, 1405–1406, 1405*f*–1406*f*
lateral and dorsolateral, 1408, 1409*f*
exposure of rib head or transverse process in, 1408, 1409*f*
incision of deep thoracolumbar fascia in, 1408, 1409*f*
retraction of longissimus lumborum muscle belly and iliocostalis lumborum muscles in, 1408, 1409*f*
skin incision for, 1408, 1409*f*
standing palpation of, 960–961
surgical anatomy for, 1404–1405, 1405*f*
Thoracolumbar spine surgery, 1404–1426
anesthetic considerations for, 1404
antibiotics for, 1404
complications in, 1410
definitions for, 1404
general considerations for, 1404–1405
healing of spinal cord in, 1408
for hemivertebra, 1415–1420
postoperative care and assessment after, 1409
preoperative management of, 1404
special age considerations in, 1410
for spinal neoplasia, 1420–1421
for spinal trauma, 1421–1425
standard surgical approaches for, 1405–1410
dorsal, 1406–1408, 1407*f*
elevation of the multifidus musculature in, 1406–1408, 1407*f*
pediculectomy in, 1404, 1408, 1408*f*
positioning for, 1406–1408, 1407*f*
removal of attachments of multifidus musculature in, 1406–1408, 1407*f*
dorsal approach to cranial and midthoracic spine, 1405–1406, 1405*f*–1406*f*
lateral and dorsolateral, 1408, 1409*f*
exposure of rib head or transverse process in, 1408, 1409*f*
incision of deep thoracolumbar fascia in, 1408, 1409*f*
retraction of longissimus lumborum muscle belly and iliocostalis lumborum muscles in, 1408, 1409*f*
skin incision for, 1408, 1409*f*
surgical anatomy for, 1404–1405, 1405*f*
Thoracolumbar spine surgery *(Continued)*
suture materials and special instruments for, 1408
for thoracolumbar disc disease, 1410–1415
Thoracoscopic ligation and division of ligamentum arteriosum, 397, 397*f*
Thoracoscopic pericardiectomy, 821–822, 823*f*
Thoracoscopy, 158, 159*b*, 163
anesthesia for, 886
for pleural effusion, 938
surgical technique for, 893
Thoracostomy
tube placement
intercostal blocks and incisional blocks for, 918*b*
preoperative concerns to, 916
small-bore wire-guided thoracostomy tubes for, 923–924, 925*f*
subcutaneous vascular access port for, 922–923, 922*f*
surgical techniques of, 922–924
trocar and large-bore thoracostomy tubes for, 922*b*, 923, 923*f*–924*f*
tube removal, 924
Thoracotomy, 889–893, 889*b*
anesthetic considerations for, 885*t*–886*t*, 886–887
in acute trauma patient, 919*t*–920*t*
of pleural effusion, 939*t*–940*t*
definition for, 884
intercostal
defined, 884
for esophageal surgery, 369–370, 371*f*
caudal, 370, 372*f*
right, 370, 372*f*
surgical technique for, 890, 891*f*–892*f*
intercostal spaces for, 889*t*
THR (total hip replacement), 1212, 1213*f*–1214*f*, 1218*t*
implant designs for, 1212–1213, 1213*f*
Thread height, of bone screws, 1017
Thread hole, for lag screw, 1019–1020
360-degree conjunctival flap, for corneal ulcers, 290, 291*f*
Three-compartment model, for evaluation of spinal trauma, 1400, 1401*f*
Three-loop pulley suture, 71, 71*f*
Thromboembolism, pulmonary, 887–888
advanced imaging modalities for, 175
after adrenalectomy, 586, 589
management of, 888*b*
Through-the-endoscope channel, esophageal dilation balloons, 162
Thumb-ring finger grip, 52, 52*f*
Thymectomy, 953–954
Thymic branchial cysts, 951–954
clinical presentation of, 951, 951*b*
definitions for, 951
diagnosis of, 951–952
diagnostic imaging of, 952
differential diagnosis of, 952–953, 953*b*
general considerations and clinically relevant pathophysiology, 951
history of, 952
laboratory findings in, 952
Thymic branchial cysts *(Continued)*
medical management of, 953, 953*b*
physical examination findings in, 952
postoperative care and assessment for, 954
prognosis of, 954
proposed staging scheme for, 951*t*
surgical technique of, 953–954, 954*b*
surgical treatment of, 953
suture materials and special instruments for, 954
Thymomas, 951–954
clinical presentation of, 951, 951*b*
definitions for, 951
diagnosis of, 951–952
diagnostic imaging of, 952, 952*f*
differential diagnosis of, 952–953, 953*b*
general considerations and clinically relevant pathophysiology, 951
history of, 952
laboratory findings in, 952
medical management of, 953, 953*b*
physical examination findings in, 952, 952*b*
postoperative care and assessment for, 954
prognosis of, 954
proposed staging scheme for, 951*t*
surgical technique of, 953–954, 954*b*
surgical treatment of, 953
suture materials and special instruments for, 954
Thyroglobulin, 615
Thyroglossal duct, 616
Thyrohyoideus muscle, 839*f*
Thyroid adenoma, 619*f*
Thyroid arteries, 616–617, 616*f*
Thyroid carcinomas, in dogs, 627–629
definitions for, 627
diagnosis of, 627–628
differential diagnosis of, 628
general considerations and clinically relevant pathophysiology, 627, 627*b*
medical management of, 628
prognosis of, 629
surgical treatment of, 628, 628*b*, 628*f*–629*f*
Thyroid cartilage, 838, 839*f*
Thyroid diverticulum, 616
Thyroid gland
feline hyperthyroidism in, 617–625
healing of, 617
surgery for, 615–629
anatomy in, 616–617, 616*f*–617*f*
anesthesia for, 616, 616*b*
antibiotics for, 616
postoperative care and assessment in, 617
preoperative management of, 615–616, 615*b*–616*b*
suture materials and special instruments for, 617
technique for, 617
Thyroid hormone, 616
Thyroid hormone (Soloxine, Thyro-Tabs, Synthroid), after hypophysectomy, 599*b*
Thyroid neoplasms, 627
Thyroid scintigraphy, 618, 618*f*–619*f*

Thyroid storm, 621, 628
Thyroid tissue, functional accessory (ectopic), 616, 618
  recurrence of hypothyroidism and, 624
Thyroidectomy
  anesthesia for, 621, 622*t*
  complication of, 620
  defined, 615
  for feline hyperthyroidism, 620
  hypocalcemia after, 624, 624*b*
  hypoparathyroidism after, 620
  intraoperative considerations for, 622*t*
  positioning for, 621
  postoperative care and assessment after, 622*t*, 624, 624*b*, 624*f*
  preoperative management of, 620–621, 620*b*, 622*t*
  techniques for, 617
    intracapsular, 621, 621*b*, 621*f*, 623*f*
      modified, 623
    modified extracapsular approach as, 623, 623*b*, 623*f*
    suture materials and special instruments for, 623–624
Thyroid-stimulating hormone (TSH), 615
Thyropharyngeus muscle, 839*f*
Thyro-Tabs (thyroid hormone), after hypophysectomy, 599*b*
Thyrotoxicosis, 617–618
Thyrotropin, 615
Thyrotropin-releasing hormone (TRH), 615
Thyrotropin-releasing hormone (TRH) stimulation test, 619
Thyroxine (T_4), 615
  free, 618–619, 619*b*
  total, 618–619
Tibia, palpation of, 965
Tibial compression test, 964–965, 965*f*, 1229, 1229*f*
Tibial crest transposition, for lateral patellar luxation, 1257
Tibial fractures, 1121–1133
  diaphyseal, 1121–1128
    definitions for, 1121
    diagnosis of, 1121
    differential diagnosis of, 1121
    general considerations and pathophysiology of, 1121
    medical management of, 1121, 1121*b*
    prognosis for, 1128
    surgical treatment of, 1121–1122, 1121*b*–1122*b*
      anesthesia for, 1122
      bone plates and screws for, 1124, 1124*b*, 1126*f*
      casts for, 1122, 1123*f*
      for comminuted fractures with large butterfly fragment, 1126, 1127*f*
      for comminuted fractures with multiple fragments, 1126, 1127*f*
      complications in, 1128
      craniomedial approach for, 1122–1123, 1122*f*–1124*f*, 1123*b*
      external skeletal fixation for, 1123–1124, 1125*f*
      interlocking nails for, 1123
      for long oblique fractures, 1126, 1127*f*
      positioning for, 1122
Tibial fractures *(Continued)*
      postoperative care and assessment, 1128
      preoperative management of, 1122
      for short oblique fractures, 1124, 1126*f*
      surgical anatomy for, 1122
      surgical technique for, 1122–1126
      suture materials and special instruments for, 1127
      for transverse fractures, 1124, 1126*f*
      type II frames, 1124, 1125*f*
  metaphyseal and articular, 1128–1131
    definitions for, 1128
    diagnosis of, 1128–1129
    differential diagnosis of, 1129
    general considerations and pathophysiology of, 1128
    medical management of, 1129
    prognosis for, 1131
    surgical treatment of, 1129
      anesthesia for, 1129
      complications in, 1131
      positioning for, 1129
      postoperative care and assessment after, 1130
      preoperative management of, 1129
      surgical anatomy for, 1129
      surgical technique for, 1129–1130, 1130*f*
      suture materials and special instruments for, 1130
  physeal, 1131–1133
    definitions for, 1131
    diagnosis of, 1131, 1131*b*
    differential diagnosis of, 1131
    general considerations and pathophysiology of, 1131
    medical management of, 1131
    prognosis for, 1133
    surgical treatment of, 1131–1132, 1131*b*
      anesthesia for, 1132
      for avulsion fractures, 1132, 1132*f*
      for displaced fractures, 1132, 1132*f*
      for nondisplaced fractures, 1132
      positioning for, 1132
      postoperative care and assessment after, 1133
      preoperative management of, 1131
      surgical anatomy for, 1132
      surgical technique for, 1132
      suture materials and special instruments for, 1132
Tibial plateau angle
  in cranial cruciate ligament rupture, 1228, 1228*f*
  defined, 1227
  measurement of, 1240, 1242*f*
Tibial plateau leveling osteotomy (TPLO), 1035*f*
  for cranial cruciate ligament rupture, 1232, 1233*f*, 1238–1240
    radiographic assessment for, 1238–1239, 1238*f*–1239*f*, 1239*t*
    surgical technique for, 1239–1240, 1240*f*–1242*f*
Tibial tuberosity
  avulsion fractures of, 1132, 1132*f*
  surgical anatomy of, 1257, 1257*f*
Tibial tuberosity advancement (TTA), for cranial cruciate ligament rupture, 1241–1243
  radiographic assessment for, 1241
  surgical technique for, 1241–1243, 1242*b*, 1244*f*
Tibial tuberosity transposition, for medial patellar luxation, 1259–1260, 1260*f*
Tibial wedge osteotomy (TWO)
  for cranial cruciate ligament rupture, 1232–1233, 1233*f*, 1240–1241
    radiographic assessment for, 1240, 1242*f*
    surgical technique for, 1240–1241, 1243*f*
Tick paralysis, 1464
Ti•cron (polyester) sutures, 62, 63*t*
Tie-in fixator, 998*f*
Tie-over bandages, 201, 201*f*–202*f*
Tigecycline (Tygacil), as drug of last resort, 82–83
Tightrope stabilization
  for coxofemoral luxation, 1224, 1225*f*
  for cranial cruciate ligament rupture, 1237–1238, 1237*f*
  for medial shoulder instability, 1168–1169, 1169*f*
Tiletamine, 127*t*–131*t*, 134–135
Time-resolved angiography with interleaved stochastic trajectories (TWIST), 174–175
Tiopronin [N-(2-mercaptopropionyl)-glycine], for urinary calculi, 705*b*
Tisseel (fibrin tissue glue), 67, 191
Tissue adhesives, 66–67, 191
Tissue core biopsy, 544, 544*f*
Tissue expanders, for skin stretching and expansion, 207–208, 209*f*
Tissue forceps, 52–53
  grip for, 53, 53*f*
  types of, 52–53, 53*f*
  uses of, 54
Tissue grafts, biologic, 68
Tissue handling, infections related to, 85
Tissue specific stem cells, 968
Tissumend II Sterile (methoxypropyl cyanoacrylate tissue adhesive), 191
Titanium/polymethylmethacrylate plate
  for Chiari-like malformation, 1356–1357, 1357*f*
  for skull defect, 1342–1343, 1344*f*
TNCC (total nucleated cell count), in peritonitis, 529–530, 530*b*
Tobramycin, 82
Tofranil (imipramine), for urinary incontinence, 714*b*
Toggle pin suture, for coxofemoral luxation, 1224, 1224*f*
Tolazoline, to reverse alpha-2 agonists, 127*t*–131*t*, 132
Tonsillectomy, 331, 338–339, 340*f*
Topical antibiotics, for wound healing, 186–187
Topical antimicrobials, for wound healing, 186–187
Topical hemostatic agents, 75–76
Topical wound medications, 186–188
  antimicrobials and antibiotics as, 186–187
  wound-healing enhancers, 187–188

Topical wound-healing enhancers, 187–188
Topiramate, for brain surgery, 1339–1340, 1339*t*
Torbutrol (butorphanol tartrate)
  for severe dyspnea, 834*b*
  for tracheal collapse, 871*b*
Torsion
  gastric, 419
  intestinal, 464–466
    definition for, 464
    diagnosis of, 465
      clinical presentation in, 465
      imaging in, 465, 465*f*
      laboratory findings in, 465
      physical examination findings in, 465
    differential diagnosis of, 465
    general considerations and clinically relevant pathophysiology, 464–465, 464*f*
    medical management of, 465
    postoperative care and assessment for, 466
    prognosis for, 466
    surgical technique for, 466
    surgical treatment of, 465–466
      anesthesia for, 466
      positioning for, 466
      preoperative management of, 465–466
      surgical anatomy for, 466
    suture materials and special instruments for, 466
  splenic, 643–645
    defined, 643
    diagnosis of, 643–644, 644*f*
    differential diagnosis of, 644
    general considerations and pathophysiology of, 643, 643*b*, 643*f*
    medical management of, 644
    postoperative care after, 645
    prognosis of, 645
    surgical technique for, 644
    surgical treatment of, 644
    suture materials and special instruments for, 645
Torticollis, 1328–1330
Total body surface area (TBSA), 238–239, 239*t*
Total ear canal ablation (TECA), 308–309, 308*b*, 310*f*–312*f*
Total elbow joint replacements, 1185
Total hepatectomy, definition for, 540
Total hip replacement, 1212, 1213*f*–1214*f*, 1218*t*
  implant designs for, 1212–1213, 1213*f*
Total intravenous (IV) anesthesia, 125
Total nucleated cell count (TNCC), in peritonitis, 529–530, 530*b*
Total parenteral nutrition (TPN), defined, 90
Tourniquets, 192–193, 193*f*
Towel clamps, 39, 39*f*
"Toweling-in", 40
TPA (tibial plateau angle)
  in cranial cruciate ligament rupture, 1228, 1228*f*
  defined, 1227
  measurement of, 1240, 1242*f*
TPLO. *see* Tibial plateau leveling osteotomy.
TPN. *see* Total parenteral nutrition.
TPO (triple pelvic osteotomy), 1212
Trabecular bone healing, 1028, 1030*f*
Trachea, 616*f*, 839*f*
  hypoplastic, 852–853, 852*b*, 852*f*
  surgical anatomy of, 839
Tracheal collapse, 868–874
  clinical presentation of, 869
  definition for, 868
  diagnosis of, 869–870
  diagnostic imaging for, 869–870
  differential diagnosis of, 870
  general considerations and clinically relevant pathophysiology, 868–869, 868*f*
  grading system for, 869–870, 870*b*, 870*f*
  laboratory findings in, 870
  medical management of, 870, 871*b*
  physical examination findings in, 869
  prognosis of, 873–874
  surgical treatment of, 870–871
    anesthesia for, 871
    complications with, 873
    endoluminal stent placement for, 872–873, 873*b*, 873*f*
    extraluminal stents for, 871–872, 872*f*
    positioning for, 871
    postoperative care and assessment for, 873
    preoperative management of, 871
    surgical anatomy for, 871
Tracheal osteochondromas, 864–865
Tracheal resection and anastomosis, 844–845, 846*f*
  complications with, 849
  defined, 833
  postoperative care after, 848
Tracheal rupture, 934–935, 934*f*
Tracheal stenosis, congenital, 868
Tracheal tumors, 864–868, 865*b*
  clinical presentation of, 865
  complications with, 868
  definition for, 864
  diagnosis of, 865–866
  diagnostic imaging for, 866, 866*f*
  differential diagnosis of, 866–867
  general considerations and clinically relevant pathophysiology, 864–865
  laboratory findings in, 866
  medical management of, 867
  physical examination findings in, 865–866
  postoperative care and assessment for, 868
  prognosis of, 868
  surgical treatment of, 867
  suture materials and special instruments for, 868
Trachealis muscle, 839
Tracheoscopy
  for laryngeal and tracheal tumors, 866, 866*b*
  for tracheal collapse, 869–870
Tracheostoma, 833
Tracheostomy, 842–844
  defined, 833
  permanent, 843–844, 845*f*
    complications of, 849
    postoperative care and assessment after, 848
Tracheostomy *(Continued)*
  temporary (tube), 842–843, 844*f*
    complications of, 849
    postoperative care after, 848
Tracheotomy, 833, 842
Tracrium. *see* Atracurium besylate.
Traction diverticula, 383
Traffic patterns, through surgical area, 18, 19*b*
Tragus, 305, 306*f*
Tramadol, 127*t*–131*t*, 133
  for cervical disc disease, 1378–1379
  for Chiari-like malformation, 1356
Tranquilizers, 125–132, 127*t*–131*t*
Transarticular fixator, for quadriceps contracture, 1291
Transconjunctival enucleation, for glaucoma, 298–299, 298*f*
Transcutaneous electrical nerve stimulation (TENS), 114, 114*b*
Transcutaneous oxygen (pO_2) monitoring ,to assess skin viability, 189–190
Transdiaphragmatic pacemaker implantation, for bradycardia
  surgical treatment of, 829
    anesthesia for, 829, 829*b*
    electrode placement in, 829, 831*f*
    midline celiotomy in, 829
    positioning for, 829
    postoperative care and assessment in, 830–831
    preoperative management of, 829
    suture materials and special instruments for, 829–830, 831*f*
    technique for, 829, 829*b*
Transfixation ligatures, for hemostasis, 75, 77*f*
Transforming growth factor-β (TGF-β), 971
Transfrontal craniotomy, 1338, 1344, 1346*f*
Transfusion reactions, 34
Transilial pins, for lumbosacral trauma, 1439, 1439*f*–1440*f*
Transitional cell carcinomas (TCCs)
  complications of, 711
  defined, 707
  diagnosis of, 709–710, 709*f*
  differential diagnosis of, 710
  general considerations and pathophysiology of, 708–709, 709*b*
  medical management of, 710, 710*b*
  postoperative care after, 711
  prognosis for, 711–712
  prostatic, 771
  surgical technique for, 711
  surgical treatment of, 710–711
Transitional vertebrae, 1431
Transitional zone, of articular cartilage, 1141–1142, 1142*f*
Translation, 1227
Transmissible venereal tumors (TVTs)
  penile, 785, 785*f*
  vaginal, 760
Transnostril core biopsies, 878
Transpalpebral enucleation, for glaucoma, 300–301, 300*f*
Transparent vapor-permeable film dressing, 200
Transpelvic urethrostomy, 694, 695*f*
Transposition flaps, 218
  for square and rectangular defects, 215, 216*f*

Transrectal fine-needle aspiration, of prostate, 742
Transrectal transverse ultrasound, of prostatic cyst, 768*f*
Transurethral biopsy, of bladder and urethral neoplasia, 710
Transvenous endocardial pacemakers, permanent, for bradycardia, 828–829
Transvenous pacing, temporary, for bradycardia, 828
Transvenous retrograde portography, 559–560, 560*b*, 560*f*
Transversalis fascia, 513*f*
Transverse canal, 1343*f*
Transverse colon, 468, 468*b*
Transverse fractures, 983–984, 984*f*
  calcaneal, 1085*f*, 1086
  direct reduction for, 990
  humeral diaphyseal, 1057–1058, 1058*f*
  mandibular, 1045, 1046*f*
  metacarpal and metatarsal, 1089*f*, 1090
  of scapular body, 1050*f*–1051*f*
  tibial diaphyseal, 1124, 1126*f*
Transverse ligament, of atlas, 1368*f*
Transverse osteotomy, 1034–1035
Transverse process, 1404–1405, 1405*f*
Transverse relaxation, 169
Transverse sinus, 1343*f*
Transverse stapling instrument, 444
Transversus abdominis muscle, 513*f*, 520
Trapezius muscle, 1049*f*
Trapezius osteomyocutaneous flap, 228, 228*f*
Trauma
  cervical spinal, 1399–1403
  evaluation for, 28–29, 29*b*, 29*f*
  of lumbosacral area, 1437–1442
  penetrating oropharyngeal, 363–365
    complications of, 365
    definition for, 363
    diagnosis of, 364
      clinical presentation in, 364
      history in, 364
      imaging in, 364, 364*f*–365*f*
      laboratory findings in, 364
      physical examination findings in, 364
    differential diagnosis of, 364
    general considerations and clinically relevant pathophysiology, 363–364
    postoperative care and assessment for, 365
    prognosis for, 365
    surgical techniques for, 364–365, 365*f*
    surgical treatment for, 364
      anesthesia for, 364
      preoperative management of, 364
      surgical anatomy for, 364
  penile and preputial, 785–786
  thoracic wall, 897–900
  thoracolumbar spinal, 1421–1425
Traumatic brain injury, 1362–1364
  definition for, 1362
  diagnosis of, 1363, 1363*f*
  differential diagnosis of, 1363
  general considerations and clinically relevant pathophysiology of, 1362–1363, 1362*f*
  medical management of, 1363
Traumatic brain injury *(Continued)*
  postoperative care and assessment for, 1364
  primary, 1362
  prognosis of, 1364
  secondary, 1362
  surgical technique for, 1364
  surgical treatment of, 1363–1364
  suture materials and special instruments for, 1364
Traumatic diaphragmatic hernia, 926–931
  clinical presentation of, 927
  definition for, 926
  diagnosis of, 927
  diagnostic imaging of, 927, 927*f*
  differential diagnosis of, 928
  general considerations and clinically relevant pathophysiology of, 926–927
  laboratory findings in, 927
  medical management of, 928
  physical examination findings in, 927
  prognosis of, 931
  surgical treatment of, 928, 928*b*
    anesthesia for, 928, 928*b*, 929*t*–930*t*
    complications with, 931
    positioning for, 928, 928*b*
    postoperative care and assessment for, 930–931
    preoperative management of, 928
    surgical technique for, 928–930, 930*b*, 931*f*
    suture materials and special instruments for, 930
Traumatic elbow luxation, 1193–1197
  definition for, 1193
  diagnosis of, 1194, 1194*f*
  differential diagnosis of, 1194
  general considerations and clinically relevant pathophysiology of, 1193–1194, 1194*b*
  medical management for, 1194, 1195*f*
  prognosis for, 1197
  surgical treatment of, 1194–1195, 1195*b*
    anesthesia for, 1195
    complications of, 1197
    elbow arthrodesis for, 1196, 1196*f*, 1197*b*
    open reduction for, 1195–1196, 1196*f*
    positioning for, 1195
    postoperative care after, 1197
    preoperative management of, 1195
    surgical anatomy for, 1195
    suture materials and special instruments for, 1197
Traumatic pneumothorax, 933–934
Traumatic proptosis, 294–296
  complications of, 296
  definition for, 294
  diagnosis of, 294
    imaging in, 294
    laboratory findings in, 294
    physical examination findings in, 294
  differential diagnosis of, 294
  general considerations and clinically relevant pathophysiology of, 294
  medical management of, 294
  prognosis for, 296
  surgical techniques for, 295, 295*f*
  surgical treatment for, 294–295
Traumatic proptosis *(Continued)*
    anesthesia for, 295
    positioning for, 295
    preoperative management of, 294–295
    surgical anatomy for, 295
  suture materials and special instruments for, 295
Treadmill gait training, as neurologic rehabilitation exercises, 122
Trephination
  defined, 880
  for nasal aspergillosis, 882, 882*f*
Trephines, 54–55
TRH (thyrotropin-releasing hormone), 615
TRH (thyrotropin-releasing hormone) stimulation test, 619
Triangular skin defects, 215, 215*f*
Triangulating end-to-end anastomoses, of small intestine, 444, 445*f*
Triangulation, in arthroscopy, 158
Triceps muscle, 1055*f*
Triceps reflex, 1334–1335, 1335*f*
Trichiasis, definition for, 266
Trichterbrust. *see* Pectus excavatum.
Triclosan, for surgical scrub, 46*t*
Trigeminal nerve
  evaluation of, 1325
    corneal reflex in, 1325, 1327*f*
    masticatory muscle atrophy in, 1325, 1326*f*
    sensation around face in, 1325, 1327*f*
  functions of, 1325*t*
Trigeminofacial reflex, 1325
Trigone, of bladder, 678, 684
Triiodothyronine (T_3), 615
Trilostane, for hyperadrenocorticism, 593, 593*b*
Trimethoprim-sulfadiazine, for *Nocardia* infection, 950*b*
Trimethoprim-sulfonamide combinations, 81*t*, 82
Tripeptide-copper complex (Iamin), for wound healing, 187
Triple antibiotic ointment, for wound healing, 186
Triple pelvic osteotomy, 1035*f*
Triple pelvic osteotomy (TPO), 1212
Tris-EDTA solution, for otitis externa, 315, 315*b*
Triseptin, for surgical scrub, 44–46, 45*f*
Trocar, in rigid endoscopy, 158
Trochanteric osteotomy, for approach to acetabulum, 1100, 1101*f*
Trochanteric physeal fracture, stabilization of, 1117
Trochlear block recession, for medial patellar luxation, 1258–1259, 1259*b*, 1259*f*
Trochlear nerve, 1324–1325, 1325*t*
Trochlear notch, 1075*f*
Trochlear wedge recession, for medial patellar luxation, 1258, 1258*f*
Tru-Cut biopsy
  of liver, 544
  of lymph, 633
TSH (thyroid-stimulating hormone), 615
TT4 (total T_4), 618–619
TTA. *see* Tibial tuberosity advancement.

Tube feeding
calculation of rate and volume of, 102, 103*b*
complications of, 103
gastrointestinal, 103
mechanical, 103
metabolic, 103
diets for, 90–93, 91*t*, 93*t*
enterostomy tube for, 101–102, 101*f*–102*f*
esophagostomy tube for, 95–97
gastrostomy tubes for, 97–101
nasoesophageal and nasogastric intubation for, 94–95, 94*b*–95*b*, 95*f*
pharyngostomy tubes for, 94
tube diameter for, 94, 94*b*
Tube gastropexy, 406–407, 407*b*, 407*f*–408*f*
Tube tracheostomy, 842–843, 844*f*
complications with, 849
postoperative care for, 848
Tubed pedicle flaps, 221–222, 222*f*
Tumbled knot, 71, 71*f*
Tumors. *see* Neoplasia.
Tunica albuginea, 727
Turbinetomy, laser-assisted, for brachycephalic syndrome, 855
TVTs (transmissible venereal tumors)
penile, 785, 785*f*
vaginal, 760
TWIST (time-resolved angiography with interleaved stochastic trajectories), 174–175
TWO. *see* Tibial wedge osteotomy.
Two-engine gait, 1365, 1382
Two-handed knots, 72, 73*f*–75*f*
Tygacil (tigecycline), as drug of last resort, 82–83
Tylenol, for discospondylitis, 1457–1458, 1458*b*
Tympanic bullae, advanced imaging modalities for, 172–174, 173*f*–174*f*
Tympanic cavity, surgical anatomy of
canine, 305, 305*f*
feline, 305, 306*f*
Tympanic membrane, 305, 305*f*
ruptured, drugs and solutions with, 302, 303*b*
Tympanostomy tubes, 319
Typhlectomy, 471, 472*f*
definition for, 466
with inverted cecum, 471, 472*f*–473*f*

U

UAP. *see* Ununited anconeal process.
Ulcer(s)
corneal, 286–291
definition for, 427
gastric, 427–430
definitions for, 427
diagnosis of, 428–429
clinical presentation in, 428–429
imaging in, 429
laboratory findings in, 429
physical examination findings in, 429
differential diagnosis of, 429
due to neoplasia, 427*f*, 428
due to NSAIDs, 428
endoscopic treatment of, 429–430
general considerations and clinically relevant pathophysiology of, 427–428, 428*b*
Ulcer(s) *(Continued)*
medical management of, 429, 429*b*
postoperative care and assessment for, 430
prognosis for, 430
surgical technique for, 430
surgical treatment of, 430, 430*b*
anesthesia for, 430
positioning for, 430
preoperative management of, 430
surgical anatomy for, 430
suture materials and special instruments for, 430
Ulna, caudal approach to, 1075, 1075*f*
Ulnar fractures
diaphyseal, 1066–1073
definitions for, 1066
diagnosis of, 1066–1067, 1067*b*
differential diagnosis of, 1067
general considerations and pathophysiology of, 1066
medical management of, 1068, 1068*b*
prognosis for, 1073
surgical treatment of, 1068–1069, 1068*b*, 1072
anesthesia for, 1069
complications of, 1073, 1073*b*
positioning for, 1069
postoperative care and assessment after, 1072–1073
preoperative management of, 1068–1069
surgical anatomy for, 1069
suture materials and special instruments for, 1072
metaphyseal and articular, 1074–1076
definitions for, 1074
diagnosis of, 1074
differential diagnosis of, 1074
distal
approaches to, 1075
stabilization of, 1075, 1076*b*, 1076*f*
general considerations and clinically relevant pathophysiology of, 1074
medical management of, 1074
prognosis for, 1076
proximal
approaches to, 1075
stabilization of, 1075, 1075*f*
surgical approach to
caudal, 1075, 1075*f*
proximal and distal, 1075
surgical treatment of, 1074–1075, 1074*b*
anesthesia for, 1074
complications of, 1076
for distal fractures, 1075, 1076*b*, 1076*f*
positioning for, 1075
postoperative care and assessment after, 1076
preoperative management of, 1074
for proximal fractures, 1075, 1075*f*
surgical anatomy for, 1074–1075
suture materials and special instruments for, 1076
physeal, 1077–1079
definitions for, 1077
diagnosis of, 1077, 1077*b*
differential diagnosis of, 1077
Ulnar fractures *(Continued)*
general considerations and pathophysiology of, 1077
medical management of, 1077
prognosis for, 1079
surgical treatment of, 1077–1078, 1077*b*
anesthesia for, 1078
complications of, 1079, 1079*f*
crossed Kirschner wires or Steinmann pins for stabilization of displaced fractures in, 1078, 1079*f*
positioning for, 1078
postoperative care and assessment after, 1078–1079
preoperative management of, 1077–1078
stabilization of nondisplaced fractures in, 1078
surgical anatomy for, 1078
suture materials and special instrument for, 1078
Ulnar growth deformities, 1079–1084
definitions for, 1079
diagnosis of, 1080, 1080*b*
differential diagnosis of, 1080
general considerations and pathophysiology, 1080
medical management of, 1080
prognosis for, 1084
surgical treatment of, 1080–1081, 1081*b*
anesthesia for, 1081
complications of, 1084
oblique osteotomy for, 1082–1083, 1083*f*
ostectomy and autogenous fat grafts for, 1081–1082, 1082*f*
partial physeal resection for, 1082, 1082*f*
positioning for, 1081
postoperative care and assessment after, 1083, 1083*b*
preoperative management of, 1081
preoperative planning for, 1081
surgical anatomy for, 1081
suture materials and special instruments for, 1083
Ulnar ostectomy, autogenous fat grafts and, 1081–1082, 1082*f*
Ulnar osteotomy
distal
for medial compartment disease, 1185
segmental, 1183
oblique, 1082–1083, 1083*f*
proximal
for medial compartment disease, 1185
segmental, 1182, 1183*f*
for ununited anconeal process, 1190–1191
Ulnaris lateralis muscle, 1075*f*
Ulnar-lengthening osteotomy, 1198–1199, 1199*b*, 1199*f*
Ulnar-shortening ostectomy, 1199, 1199*b*, 1199*f*
Ultra Clorox, as disinfectant, 20*t*
Ultrasonic cleaning, of instruments, 56–58
Ultrasonic Doppler flow detection, to assess skin viability, 189–190
Ultrasonographic biopsy, of small intestine, 437

Ultrasonography
of intestinal intussusception, 460
of intestinal masses, 434
of pancreatitis, 600
of portosystemic shunts, 552–553, 552*f*
therapeutic, 112–113, 112*f*, 113*b*
Ultrasound-guided biopsy
percutaneous
of kidney, 654, 655*f*
of liver, 545
prostatic, 742
Ultrasound-guided percutaneous prostatic drainage, 766, 766*f*
Umbilical artery, 689*f*, 727*f*
Umbilical cord, of flexible endoscope, 158, 160–161, 161*f*
Umbilical hernia, 518–522
definitions for, 518–519
diagnosis of, 519–520
differential diagnosis of, 520
false, 518–519
general considerations and clinically relevant pathophysiology of, 519
location of, 519, 519*f*
medical management of, 520
paracostal, 519, 519*f*, 521
prognosis for, 522
surgical management of, 520–521, 520*f*
true, 518–519
UMN (upper motor neuron) paresis/plegia, 1332
Unconscious proprioception, 1332–1333
Undermining, of skin, for tension relief, 206
Underwater treadmill, 122–123, 122*b*, 123*f*
Unilateral advancement flaps, 216*f*
Unilateral-biplanar (type Ib) fixator, 998*f*, 1001
Unilateral-uniplanar (type Ia) fixator, 998*f*, 1001, 1001*b*
United States Pharmacopeia (USP) suture sizes, 60, 61*t*
Ununited anconeal process (UAP), 1174*t*, 1188–1191
definition for, 1188
diagnosis of, 1189, 1189*b*, 1189*f*
differential diagnosis of, 1189
general considerations and clinically relevant pathophysiology of, 1188–1189
medical management of, 1189
prognosis for, 1191, 1191*b*
surgical treatment of, 1189
anesthesia for, 1190
combined medial approach, for removal of the anconeal process and medial coronoid process, 1190, 1191*f*
complications of, 1191
lag screw fixation for, 1190–1191, 1191*f*
lateral approach, for removal of the anconeal process, 1190, 1190*f*
positioning for, 1190
postoperative care after, 1191
preoperative management of, 1190
surgical anatomy for, 1190
suture materials and special instruments for, 1191
ulnar osteotomy for, 1190
Ununited coronoid process. *see* Fragmented coronoid process.
UPP (urethral pressure profile)
for ectopic ureter, 666
for urinary incontinence, 722
Upper airway examination, anesthetic considerations for, 834–836, 835*t*
Upper motor neuron (UMN) paresis/plegia, 1332
Upper respiratory system surgery, 833–883
anesthesia for, 834–837, 835*t*, 836*b*
antibiotics for, 837, 838*b*
for brachycephalic syndrome, 849–856
complications of, 848–849, 848*b*
definitions for, 833
for epiglottic retroversion, 863–864
healing after, 846–847
indications for, 834*b*
for laryngeal and tracheal tumors, 864–868
for laryngeal collapse, 856–858
for laryngeal paralysis, 858–863
for nasal aspergillosis, 880–883
for nasal tumors, 874–880
postoperative care and assessment for, 847–848
preoperative management of, 833, 833*b*, 834*f*
special age considerations to, 849
surgical anatomy for, 837–839, 838*f*–839*f*
surgical technique for, 839–846
for rhinotomy, 839–841
for tracheal resection and anastomosis, 844–845, 846*f*
for tracheostomy, 842–844
for tracheotomy, 842
for ventriculocordectomy, 845–846
suture materials and special instruments for, 847
for tracheal collapse, 868–874
Upper respiratory tract, healing of, 846–847
Urate calculi, 701
treatment and prevention of, 702*t*
Urecholine (bethanechol), to improve urination, 701*t*
Ureidopenicillins, 80
Ureter(s), 650–677
anatomy of, 727
definitions for, 650
ectopic, 663–669
bilateral, 664
diagnosis of, 664–666
history in, 665, 665*b*–666*b*
imaging in, 665–666, 665*f*–666*f*, 666*b*
laboratory findings in, 666
physical examination in, 665
signalment in, 664–665
diagnosis of, cystoscopy for, 712, 713*f*
differential diagnosis of, 666
extraluminal (extramural), 663, 664*f*
general considerations and pathophysiology of, 663–664, 663*f*–664*f*
intraluminal (intramural), 663, 664*f*
medical management of, 666, 666*b*
postoperative care and assessment for, 668, 669*b*
Ureter(s) *(Continued)*
prognosis for, 669
surgical technique for, 667
cystoscopically-guided laser ablation as, 667
neoureterostomy as, 667, 668*f*
ureteroneocystostomy as, 667, 669*f*
surgical treatment of, 666–667, 667*b*
suture materials and special instruments for, 667
healing of, 662, 662*b*
surgical anatomy of, 653–654
surgical technique for, 654–662
for neoureterostomy, 662
for pyelolithotomy, 657, 658*f*
for subcutaneous ureteral bypass system, 662
for ureteral anastomosis, 659–660, 661*f*–662*f*
for ureteral reimplantation, 658–659, 660*f*
for ureteroneocystostomy, 662
for ureteronephrectomy, 655–656, 656*b*, 656*f*
for ureterotomy, 657–658, 658*b*, 659*f*
surgical treatment of
anesthetic considerations with, 650–653, 652*t*–653*t*
antibiotics with, 653, 653*b*
complications of, 663
intraoperative considerations for, 652*t*–653*t*
postoperative care after, 652*t*–653*t*, 662–663
preoperative management of, 650, 652*t*–653*t*
special age considerations with, 663
suture materials and special instruments for, 662
Ureteral anastomosis, 659–660, 661*f*–662*f*, 694, 696*f*
Ureteral calculi, 669–673
complications of, 672
definitions for, 669
diagnosis of, 670–671, 670*b*
differential diagnosis of, 671
general considerations and pathophysiology of, 669–670
medical management of, 671
postoperative care and assessment for, 672
prognosis for, 672
special age considerations for, 672
surgical technique for, 672, 672*b*
surgical treatment of, 671–672, 672*b*
suture materials and special instruments for, 672
Ureteral ectopia. *see* Ureter(s), ectopic.
Ureteral neoplasia, 673–675
complications of, 675
definition for, 673
diagnosis of, 674
differential diagnosis of, 674
general considerations and pathophysiology of, 673–674, 673*b*–674*b*
medical management of, 674
postoperative care and assessment for, 675

Ureteral neoplasia *(Continued)*
prognosis of, 675
special age considerations for, 675
surgical technique of, 675
surgical treatment for, 674–675, 675*f*
suture materials and special instruments for, 675
Ureteral openings, bilateral, 664, 664*f*
Ureteral reimplantation, 658–659, 660*f*
Ureteral rupture, 699
Ureteral stenting, 672–673, 673*f*
Ureteral troughs, 664, 664*f*
Ureteroceles, 663–664, 663*f*
Ureterolithiasis, 669
Ureterolithotomy, 669
Ureteroliths, 669
Ureteroneocystostomy
defined, 650
for ectopic ureters, 667, 669*f*
surgical technique for, 662
Ureteronephrectomy, 655–656, 656*b*, 656*f*
Ureteroplasty, bladder-flap, 659, 661*f*
Ureterotomy, 650, 657–658, 658*b*, 659*f*, 669
Urethra, 678–719, 727
definitions for, 678
feline idiopathic cystitis of, 717–719
healing of, 696
hypoplastic, bladder flap reconstruction of, 716, 716*f*–717*f*
membranous (pelvic), 684–685, 684*f*
penile, 684–685, 684*f*
prostatic, 684–685, 684*f*
surgical anatomy of, 684, 684*f*–686*f*
surgical technique for, 684–696, 685*f*–686*f*
cystostomy (prepubic catheterization) as, 685–686, 687*f*
cystotomy as, 685–687, 685*b*, 687*f*
intrapelvic urethral anastomosis as, 686–687, 689*f*
urethrostomy as, 688–694
urethrotomy as, 687–688, 687*b*
urinary diversion as, 694–696, 696*f*
surgical treatment of
anesthesia for, 679–684, 680*t*–684*t*
antibiotics for, 684, 684*b*
complications of, 697
postoperative care after, 696–697
preoperative management of, 678–679, 679*b*, 679*f*
special age considerations with, 697–698
suture materials and special instruments for, 696, 696*b*
vascular and nerve supply, 689*f*
urinary incontinence of, 712–717
uroabdomen of, 698–700
Urethral anastomosis, intrapelvic, 686–687, 687*f*, 689*f*
Urethral artery, 689*f*, 727*f*
Urethral branch, 689*f*
Urethral calculi, 700–705
definitions for, 700
diagnosis of, 702–703
history in, 703
imaging in, 703, 703*b*, 703*f*
laboratory findings in, 703, 703*b*
Urethral calculi *(Continued)*
physical examination in, 703
signalment in, 702–703, 702*b*
differential diagnosis of, 703
general considerations and pathophysiology of, 701, 701*b*–702*b*, 702*f*, 702*t*
medical management of, 703–704, 704*f*
prognosis for, 705
surgical technique for, 705
surgical treatment of, 704–705
anesthesia for, 705
complications of, 705
laparoscopically assisted cystoscopy for, 704
lithotripsy for, 704
positioning for, 705
postoperative care after, 705, 705*b*
preoperative management of, 704–705, 705*b*
stone analysis in, 704*b*
surgical anatomy for, 705
suture materials and special instruments for, 705
Urethral discharge, 720
Urethral neoplasia, 707–712
complications of, 711
definitions for, 707
diagnosis of, 709–710, 709*f*
differential diagnosis of, 710
general considerations and pathophysiology of, 708–709, 709*b*
medical management of, 710, 710*b*
postoperative care after, 711
prognosis for, 711–712
surgical technique for, 711
surgical treatment of, 710–711, 711*f*
suture materials and special instruments for, 711
Urethral pressure profile (UPP)
for ectopic ureter, 666
for urinary incontinence, 722
Urethral prolapse, 705–707
complications of, 707
definitions for, 705
diagnosis of, 706, 706*b*, 706*f*
differential diagnosis of, 706
general considerations and pathophysiology of, 705
medical management of, 706
postoperative care after, 707
prognosis for, 707
surgical technique for, 706–707
resection as, 706–707, 707*f*
urethropexy as, 707, 708*f*
surgical treatment of, 706
suture materials and special instruments for, 707
Urethral reconstruction, for hypospadias, 776
Urethral rupture, 698
diagnosis of, 698–699
differential diagnosis of, 699
medical management of, 699–700, 700*b*
prognosis of, 700
surgical treatment of, 700
complications of, 700
postoperative care after, 700, 700*b*, 701*t*
Urethral rupture *(Continued)*
suture materials and special instruments for, 700
Urethral trauma, preoperative management of, 679, 680*f*
Urethrography, retrograde, of uroliths, 703, 703*b*, 703*f*
Urethropexy
for urethral prolapse, 707, 708*f*
for urinary incontinence, 714–715, 715*f*
Urethrostomy, 688–694
defined, 678
perineal
canine, 689–690, 692*f*
feline, 690–692, 693*f*
prepubic (antepubic), 692, 694*f*
prescrotal, 688–689, 691*f*
scrotal, 689, 691*f*–692*f*
subpubic, 692–694, 694*f*–695*f*
transpelvic, 694, 695*f*
Urethrotomy, 687–688, 687*b*
defined, 678, 700
perineal, 688, 690*f*–691*f*
prescrotal, 687–688, 690*f*
Urinary calculi, 669, 700
Urinary diversion, 694–696, 696*f*
Urinary incontinence, 712–717
after reproductive surgery, 720, 745, 746*b*
definitions for, 712
diagnosis of, 712–713, 713*f*
differential diagnosis of, 713
general considerations and pathophysiology of, 712, 712*b*
medical management of, 713–714, 714*b*
prognosis for, 717
surgical technique for, 714–716
artificial urethral sphincter placement as, 716, 716*f*
bladder flap reconstruction of hypoplastic urethra as, 716, 716*f*–717*f*
colposuspension as, 714
cystourethropexy as, 714–715, 715*f*
endoscopic collagen injection as, 715, 715*f*
surgical treatment of, 714, 714*b*
complications of, 716
postoperative care after, 716
suture materials and special instruments for, 716
Urinary leakage
drugs used for, 666, 666*b*
preoperative management of, 678, 679*f*
Urinary obstruction
anesthetic considerations with
in compromised patient, 681*t*–682*t*
in trauma patient, 682*t*–684*t*
in uncompromised patient, 680*t*–681*t*
preoperative management of, 678
Urinary sphincter leakage
drugs used for, 666, 666*b*
preoperative management of, 678, 679*f*
Uroabdomen, 698–700
definitions for, 678, 698
diagnosis of, 698–699, 698*b*, 699*f*
differential diagnosis of, 699
general considerations and pathophysiology of, 698, 698*b*

Uroabdomen *(Continued)*
medical management of, 699–700, 700*b*
surgical treatment of, 700, 701*t*
suture materials and special instruments for, 700
Urodynamic evaluation, for ectopic ureter, 666
Uroepithelium, healing of, 662, 662*b*
Urogenital artery, 726–727, 727*f*
Urography
CT-based excretory, 174–175
excretory, 665, 665*f*, 666*b*
for ureteral rupture, 699*f*
for urinary incontinence, 713
Urohydropropulsion, voiding, for bladder and urethral calculi, 704
Urolithiasis
defined, 669, 700
treatment and prevention of, 701, 702*t*
Uroliths, 669, 701
Uroperitoneum. *see* Uroabdomen.
USP (United States Pharmacopeia) suture sizes, 60, 61*t*
Uterine adenocarcinomas, 751
Uterine arteries, 725–726
Uterine contraction, drugs that initiate, 738, 738*b*
Uterine leiomyoma, 751, 751*f*
Uterine leiomyosarcoma, 751
Uterine neoplasia, 751–752
definitions for, 751
diagnosis of, 751–752
differential diagnosis of, 752
general considerations and clinically relevant pathophysiology of, 751, 751*b*, 751*f*
medical management of, 752
prognosis for, 752
surgical treatment of, 752
anesthesia for, 752, 753*t*–754*t*
positioning for, 752
postoperative care and assessment of, 752
preoperative management of, 752
prognosis for, 752
surgical technique for, 752
Uterine prolapse, 761–762
definitions for, 761
diagnosis of, 761
differential diagnosis of, 761
general considerations and clinically relevant pathophysiology of, 761
medical management of, 761
prognosis for, 762
surgical treatment of, 761–762, 761*b*
Uterine tube, 725–726
Uterus, 725–726
Uveitis, anterior, 281

V

Vacuum-assisted drainage, of skin grafts, 234
Vagina, 725–726
Vaginal artery, 689*f*
Vaginal edema. *see* Vaginal prolapse/hyperplasia/tumor.
Vaginal flora, normal, 720, 721*b*
Vaginal fold prolapse. *see* Vaginal prolapse/hyperplasia/tumor.
Vaginal hemorrhage, endoscopy for, 160
Vaginal hypertrophy. *see* Vaginal prolapse/hyperplasia/tumor.
Vaginal leiomyoma, 740*f*
Vaginal prolapse/hyperplasia/tumor, 759–761
definitions for, 759
diagnosis of, 759
differential diagnosis of, 759, 760*f*
general considerations and clinically relevant pathophysiology of, 759, 759*b*
medical management of, 760
prognosis for, 761
surgical treatment of, 760
Vaginography, 721
Vaginoscopy, 158
for uterine neoplasia, 752
Vagus nerve, 795, 1325–1328, 1325*t*, 1328*f*–1329*f*
Valgus angulation, 1252
Valgus deformity, 958*b*, 1032, 1033*f*
Valgus malalignment, of tibia, 1124, 1125*f*
Valgus position, of foot, 1084
Valium. *see* Diazepam.
Vancomycin, as drugs of last resort, 82–83
Vapor phase hydrogen peroxide plasma sterilization, 8–9, 9*f*
Varus angulation, 1252
Varus deformity, 958*b*, 1032, 1033*f*
Varus malalignment, of tibia, 1124
Varus position, of foot, 1084
Varus stress test, 1250
Vascular access port, for pleural effusion, 922–923, 922*f*
Vascular anastomoses, sutures for, 66, 66*f*–67*f*
Vascular disease, advanced imaging modalities for, 174–175, 174*f*–175*f*
Vascular endothelial growth factor (VEGF), 971
Vascular nonunion, 1031–1032
Vascular ring anomalies, 394–398
complications of, 398
diagnosis of, 395–396
clinical presentation in, 395
imaging in, 395–396, 396*f*
laboratory findings in, 396
physical examination findings in, 395
differential diagnosis of, 396
general considerations and clinically relevant pathophysiology of, 394–395, 395*b*
medical management of, 396
postoperative care and assessment for, 397–398
prognosis for, 398
surgical technique for, 397
surgical treatment of, 396–397
anesthesia for, 396
positioning for, 397
preoperative management of, 396
surgical anatomy for, 396
Vasectomy, 735, 737*f*
complications of, 745*b*
defined, 720
Vasoconstriction, in wound healing, 179–180
Vasodilators, for cardiac disease, 789*b*
Vasopressors, for cardiac disease, 789*b*
Vasotec (enalapril)
for cardiac disease, 789*b*
for congestive heart failure, 809*b*
Vastus intermedius muscle, 1290
Vastus lateralis muscle, 1112*f*, 1257*f*, 1290
Vastus medialis muscle, 1257*f*, 1290
Vecuronium
for cesarean section, 725*t*–726*t*
for fracture repair, 977*t*–978*t*
Velpeau slings, for scapulohumeral joint luxation, 1167
Vena cava, 543*f*
caudal, 543*f*, 556, 794–795, 794*f*
abnormalities of, 556, 556*b*
cranial, 794–795, 794*f*
Venereal tumors, transmissible
penile, 785, 785*f*
vaginal, 760
Venous carbon dioxide ($PvCO_2$), during brain surgery, 1340
Venous congestion, in flap, 218
Venous inflow occlusion
defined, 788
drugs for, 788–793, 793*b*
open patch-graft correction with, 807, 808*f*
surgical technique for, 788, 795, 795*f*–796*f*
Venous sinuses, 1405
Vented drains, 191
Ventilation, after cardiac surgery, 797
Ventilation/perfusion ($\dot{V}_A/\dot{Q}$) mismatch, 797
Ventral bulla osteotomy, 310, 313*f*
Ventral meatus, 838*f*
Ventral midline celiotomy
in cats and female dogs, 516, 516*f*
in male dogs, 516–517, 516*f*
Ventral nasal conchae, 838*f*
Ventral slot procedure, 1365, 1367–1370, 1370*f*
cranial and caudal extent of ventral slot defect in, 1367–1370
decompression completed in, 1367–1370, 1371*f*
depth of ventral slot defect in, 1367–1370, 1371*f*
excision of ventral annulus in, 1367–1370, 1370*f*
venous sinuses and vertebral artery in, 1367–1370, 1371*f*
Ventricular arrhythmias, with gastric dilatation-volvulus, 423–424
Ventricular septal defect (VSD), 811–813
definitions for, 811
diagnosis for, 811
differential diagnosis for, 811
general considerations and clinically relevant pathophysiology of, 811
medical management of, 811
prognosis for, 813
surgical treatment of, 811–812, 812*f*
Ventriculocordectomy, 845–846
bilateral, via ventral laryngotomy, 862
complications of, 849
defined, 833

Ventriculocordectomy *(Continued)*
with laryngotomy approach, 845–846, 847*f*
with oral approach, 845, 846*f*
Ventriculoperitoneal shunt placement, for congenital hydrocephalus, 1349, 1350*f*
Ventrocaudomedial nucleus, of thalamus, 141–142
Ventroversion, angle of, 1209
Vertebra(e)
butterfly, 1415
transitional, 1431
Vertebral arch malformation, 1381*t*
Vertebral artery, 1367
Vertebral body fracture, CT of, 173*f*
Vertebral body pins, for hemivertebra, 1418, 1419*f*
Vertebral fractures. *see* Lumbosacral trauma.
Vertebral index, 908, 908*b*, 908*f*, 908*t*
Vertebral physitis, 1457
Vertebral sinus venography, of degenerative lumbosacral stenosis, 1432–1433
Vertebral tipping, 1381*t*
Vertical ear canal ablation, 307–308, 308*f*–309*f*
Vertical ear canal graft repair, for acquired oronasal fistula, 350–351, 354*f*
Vertical mattress suture pattern, 69, 69*f*
Vertical mattress sutures, 209–210
Vesicants, chemical injuries due to, 241
Vessel ligation
for hemostasis, 75
ligating clips for, 67
Vessel sealing system, 78
Vessels, sutures for, 66, 66*f*–67*f*
Vestibular ataxia, 1331–1332, 1332*b*
Vestibular dysfunction, associated with otitis interna, 316, 316*b*
Vestibular fold, 838–839, 839*f*
Vestibular function, evaluation of, 1325
Vestibulocochlear nerve, 1325, 1325*t*, 1327*f*
Vet BioSISt (porcine small intestinal submucosa) grafts, 68
Vetbond (cyanoacrylate tissue adhesives), 66–67, 191
Vetcassette II (polymerized caprolactam) sutures, 63*t*
Vetmedin (pimobendan)
for cardiac disease, 789*b*
for congestive heart failure, 809*b*
Vetspon, for hemostasis, 75
Vibramycin. *see* Doxycycline.
Vicryl (polyglactin 910) surgical mesh, 68
Vicryl (polyglactin 910) sutures, 62, 63*t*
Video-assisted thoracic surgery, 893
Vincristine, for transmissible venereal tumors, 760
Vinyl nail caps (SoftPaws), 257
Viokase, for exocrine pancreatic insufficiency, 606*b*
Virkon S, as disinfectant, 20*t*
Visceral pleura, 916, 937
Viscerovisceral reflex arc theory, 143–144
Vision
assessment of, 1324–1325, 1326*f*
neuroanatomic pathways for, 1324–1325, 1326*f*
Vitamin D, for hypocalcemia after thyroidectomy, 624, 624*b*
Vitamin K1 (AquaMephyton, Mephyton), for extrahepatic bile duct obstruction, 571, 572*b*
Vivostat (autologous fibrin glue), 67
Vocal folds, 838, 839*f*
Voiding urohydropropulsion, for bladder and urethral calculi, 704
Volvulus
gastric dilatation-. *see* Gastric dilatation-volvulus.
intestinal, 464–466
definition for, 464
diagnosis of, 465
clinical presentation in, 465
imaging in, 465, 465*f*
laboratory findings in, 465
physical examination findings in, 465
differential diagnosis of, 465
general considerations and clinically relevant pathophysiology of, 464–465, 464*f*
medical management of, 465
postoperative care and assessment for, 466
prognosis for, 466
surgical technique for, 466
surgical treatment of, 465–466
anesthesia for, 466
positioning for, 466
preoperative management of, 465–466
surgical anatomy for, 466
suture materials and special instruments for, 466
Vomiting, 365
after removal of gastric foreign body, 419, 419*b*
induction of, for gastric foreign bodies, 418, 418*b*
von Langenbeck technique, for cleft palate repair, 344, 344*f*
von Willebrand factor/antigen, in hypothyroidism, 615
Voxels, 170
VSD. *see* Ventricular septal defect.
$\dot{V}_A/\dot{Q}$ (ventilation/perfusion) mismatch, after cardiac surgery, 797
V-to-Y plasty, 210, 212*f*, 218
Vulva, 725–726
Vulvar skin folds, 252, 254*f*
Vulvoplasty, 740–741, 741*f*
complications of, 745*b*
defined, 720
positioning for, 740–741

W

Walking
backwards, 120
incline, 120
ladder, 121
Walking sutures, 209, 210*f*
Warfarin
international normalized ratio (INR) for, 888, 888*b*
for pulmonary thromboembolism, 888*b*

biologic, 197*t*–198*t*
characteristics of, 194, 194*b*
foam, 197*t*–198*t*, 199
impregnated with iodine, 200
interactive, 196
maltodextrin, 197*t*–198*t*
miscellaneous, 197*t*–198*t*
nonadherent, 196, 196*b*
calcium/calcium-sodium alginate, 197*t*–198*t*, 199
hydrocolloids, 197*t*–198*t*, 199
hydrogel, 197*t*–198*t*, 198–199
hypertonic saline, 196–198, 197*t*–198*t*
occlusive, 196, 197*t*–198*t*
Wound dressing(s) *(Continued)*
paraffin-impregnated, 196, 197*t*–198*t*
perforated polyester film with cotton, 197*t*–198*t*
petroleum-impregnated, 196, 197*t*–198*t*
polyurethane films, 196, 197*t*–198*t*
rayon/polyethylene glycol, 197*t*–198*t*
semiocclusive, 196, 197*t*–198*t*
types of, 197*t*–198*t*
selection of
based on purpose, 195, 196*t*
based on wound characteristics, 195, 197*t*
silver-impregnated, 197*t*–198*t*, 200
Wound healing, 179–183
complications, 194
external factors affecting, 183
growth factors in, 179, 180*b*
host factors affecting, 182
moist, 182
phases of, 179–182
débridement, 180
inflammatory, 179–180, 180*b*
maturation, 181–182
repair, 180–181
primary, 193
by secondary intention, 193–194
wound characteristics affecting, 182–183
Wound infection, with animal bite wounds, 243–244, 244*b*
Wound lavage, 184, 185*f*
Wound management, 179–194
assessment of skin viability in, 189–190
burn, 239–240, 240*f*
fundamentals of, 183, 183*b*
initial, 184, 184*t*, 185*f*
for open or superficial wounds, 183–186
antibiotics in, 186
debridement in, 185–186
autolytic, 182, 185
bandage (mechanical), 185
biosurgical, 186
enzymatic, 185–186
surgical, 185
hyperbaric oxygen therapy in, 189
low-level laser therapy in, 189
pulsed electromagnetic field in, 189
topical wound medications in, 186–188
topical wound-healing in, 187–188
wound cleansers in, 184, 184*t*, 188–189
wound lavage in, 184, 185*f*
postoperative, 194
surgical anatomy and, 179
wound closure. *see* Wound closure.
wound healing and. *see* Wound healing.
Wound-healing enhancers, topical, 187–188
Woun'Dres Collagen Hydrogel (hydrolyzed bovine collagen), 188
Wrapping materials, for surgical packs, 12, 12*t*
W-type forceps, 161, 162*f*
WW (window width), 170

X
Xanthochromia, 1321–1322
X-Banders (skin stretcher), 208, 209*f*
Xenogeneic stem cell, 971
Xenografts, 232–233
Xenon lamps, for arthroscopy, 167
Xeroform (petroleum-impregnated with bismuth tribromophenate), 196, 197*t*–198*t*
Xiphoid process, 888–889, 889*f*
X-shaped suture line, for square and rectangular skin defects, 215, 216*f*
Xylazine (Rompun)
for brain surgery, 1342
for induction of vomiting, for gastric foreign bodies, 418, 418*b*
for premedication, 127*t*–131*t*, 134–135
Xylenol orange stain, to assess skin viability, 189–190
Xylocaine. *see* Lidocaine.

Y
Y-fractures of elbow, stabilization of, 1065, 1066*f*
Yohimbine, to reverse alpha-2 agonists, 127*t*–131*t*, 132
Yorkshire terrier encephalitis, 1453
Y-shaped suture line, for triangular skin defects, 215, 215*f*
Y-U pyloroplasty, 405–406, 406*b*, 407*f*

Z
Zefazone (cefmetazole), for perineal, rectal, or colonic surgery, 467–468, 468*b*
Zelapar (selegiline), for cognitive dysfunction syndrome, 1445–1447
Zepp procedure, 306, 306*f*
Zestril (lisinopril), for cardiac disease, 789*b*
Zithromax (azithromycin), 81*t*
for lyme disease, 1150*b*
Zofran (ondansetron), for vomiting after removal of gastric foreign body, 419, 419*b*
Zolazepam, for premedication, 127*t*–131*t*, 131
Zollinger-Ellison syndrome, 427
defined, 599–600, 612
gastric ulceration and erosion due to, 428
Zone of calcified cartilage, 1141–1142, 1142*f*
Zonisamide, for brain surgery, 1339–1340, 1339*t*
Z-plasty, 210–211, 212*f*
for quadriceps contracture, 1291
Zubrin (tepoxalin), 148*t*–149*t*, 150
Zygomatic mucocele, 358
Zygomatic salivary gland, 361, 361*b*, 361*f*
excision of, 363
Zyloprim (allopurinol), for urinary calculi, 705*b*
Zyvox (linezolid), as drug of last resort, 82–83
